### **IMPORTANT:**

The BM15A amplifier has been redesigned: the "Mk. II" version.

The main differences are:

- Low voltage supply has now its own secondary taps on the transformer.
- Voltage selector is now a rotary switch type.
- New test points added.
- Test point numbers are changed (Please refer to the schematics).
- Mounting depth. Capacitors C2 and C3 are higher than on the Mk.I module  
- a Mk. II module does NOT fit into a speaker cabinet designed for a Mk. I module.

BM15As with serial no. LOWER than 695960 are fitted with the Mk. II module,  
- however exceptions might occur...

## BM15A Active Nearfield Monitor - Service Manual

### **Precautions:**

Servicing should be undertaken only by a qualified person and in a proper workshop environment, with anti-static precautions taken and a full compliment of tools and instruments.

If powering up the module out of its cabinet beware of mains voltage on the mains connector, switches and capacitor.

### **Possible Faults**

If a single LF or HF drive unit seems to have failed then remove and test it. However, if there is no output at all, the amp module may be faulty.

If no LED is lit then first check the mains fuse and replace it with the correct value for the mains voltage used if necessary, if the mains fuse is intact the internal fuses may have blown.

If the red LED is lit it means that the power MOSFET mounting bracket has overheated (more than 70°C) or a DC voltage has arisen at an amp output.

### **Disassembly**

The drive units and the amp module are held in place using Allen head M4 bolts. These should be moderately tight; the factory setting is correct, do not over-tighten.

### **Drive Units**

Support the weight of the drivers while removing the bolts; they must not hang on their wires. The color code for the bass driver is red to the positive terminal and black to the negative; the tweeter wiring is blue to the positive and black to the negative. The black wires are interchangeable. Be careful not to bring anything into contact with the diaphragms, especially the tweeter, which is easily damaged.

### Replacement Driver Part Numbers

Driver	Description	DA Item No.	TC order code
Tweeter	D-260 DA with protector	81622	795005011
Woofer	24W100XL04 DA	87581	795026011

### **Amp Module**

The amp module can be taken out with the cabinet face down if it is certain that nothing impinges on the drive units or LED's, but it is best removed with the speaker standing vertically on a solid support with access all round. The bolts should first be loosened so that they can subsequently be removed with one hand while supporting the weight of the module (it's heavy) with the other hand by holding the heatsink.

When all the bolts are out, withdraw the module a little way and unlatch the small 4-pin connector and LED cable at the top of the circuit board. The large 4-pin connector with speaker wires towards the bottom of the board needs to be rocked slightly from side to side while disconnecting, taking care not to bend the pins.

## **Fault Finding**

If powering up the module out of its cabinet beware of mains voltage on the mains connector, switches and capacitor.

Connect the extension lead for the LED's but not for the drive units. Inspect the on-board fuses. If they are blown the likely cause is failed output MOSFETs.

To test the MOSFETs, look for a low resistance between positive and negative power rails, putting meter probes on the sources of a pair of MOSFETs (pinout: 1-gate, 2-drain, 3-source. Please refer to figure 1) or on the right hand side terminals of R2 & R3. Both MOSFETs in an output pair will usually fail and to trace which pair, test for a low gate/source or gate/drain resistance. These devices effectively go to short circuit when blown. Replace MOSFETs in pairs.

N.B. Q14 & Q15 must be replaced with a matched pair which must be obtained from the manufacturer.

The drain resistors R60, R61, R90, R91, R102, R103 and the driver transistors Q6, Q8, Q10, Q13 should be tested if the MOSFETs are blown.

If the HF amp MOSFETs has failed please test the HF limiter circuit Zeners (ZD8 & ZD9) with a diode tester and test the lightbulb (LDR1-A) with a resistance tester.

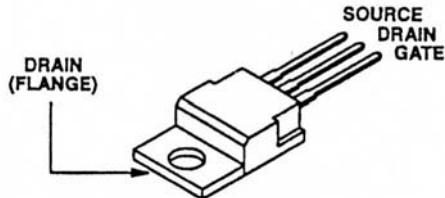

Figure 1 -Pin configuration of Transistors in BM6A

A rare fault might be for example the failure of a single MOSFET or a driver transistor or op-amp, or the relay drive circuit itself may be faulty.

If the module can be powered up without blowing the on-board fuses, check PSU voltages on R2 and R3. Voltages on the right hand side terminals are nominally +/-51V, and on the left hand side, +/-28V. The low voltage power supply is +/-12V measured at the supply pins of the op-amps. If PSU voltage (close to +/-15V) appears on any of the op-amp outputs (pins 1 & 7 on U1 - U6), this would show a fault in the signal handling circuitry.

To find a DC voltage at a power amp output, measure the voltages on the MOSFET mounting tabs, these are connected to their drains which are effectively the output, and are close to 0V when the circuit is working properly.  
DC voltage can't be measured at the output terminals because these will be out of circuit if the relay is open.

## **Replacing Components**

To remove the PCB desolder the transformer and XLR wires. Remove the thermal switch nut and bolt and the MOSFET mounting clip screws, not allowing the clips to rotate. Desolder the XLR connector wires, remove the screws holding the board and lift it off. The heatsink mounting pads may have stuck the MOSFETs to the bracket, if so, put a small screwdriver to the edge of each MOSFET and gently tap it sideways to free it.

If MOSFETs are to be replaced, make sure they sit at exactly the same height and reach as the original devices. It is essential for reliability to ensure that the MOSFETs have a proper, high pressure mounting to the heatsink.

Bend the pins of the MOSFETs in order to get correct position before mounting/soldering using a flatnose plier without stressing the devices.

LDR/Lightbulb assembly: Solder the LDR on the circuit board and bend the legs of the bulb so the bulb lies flat on top of the LDR. Solder the bulb and fit the heatshrink tube on top. Shrink the tube and while the glue in it is still hot, close the top with a flat nose plier forming a light tight "hat" for the lamp/LDR.

### **Reassembly**

Replace the board and the securing screws leaving a little vertical play. Use high efficiency heatsink pads (Bergquist Sil-Pad K-10-43) to mount the MOSFETs and thermal switch. Make sure the mounting clips are level and tighten them all the way.

Resolder the transformer and XLR wires. Finally locate the heads of thermistors R54 and R85 inside the mounting tab holes of their respective MOSFETs, and apply ample heatsink paste in the hole and around the heads.

### **Setting Quiescent Current**

Install T1A fuses in case there is a fault remaining. Check that there is a high resistance between +51V and -51V power rails, and set the Iq preset (VR1 / VR2) on the channel whose devices have been replaced, to zero resistance. N.B. Grey 10mm presets have zero resistance turned clockwise. blue 6mm presets -anticlockwise. Check for zero resistance across thermistor terminals.

Power up the module monitoring the voltage between test points for the faulty / replaced section.

The mains voltage must be 230V ( or 115V if selected ) and should be monitored during setting of the quiescent current. If it is found to be more than 2% out, a variac should be used to set it correctly. The Iq settings have an NTC characteristic, i.e. the tendency is for current to reduce as temperature increases. For example, when the module has been driven hard for a period of time and is quite hot, the settings will be up to 20% down.

The quiescent current must be re-adjusted about two minutes after switch on from cold.

The voltage in the HF section is to be set to

Mk. I module:	TP2-TP1	28mV
Mk. II module:	TP7-TP8	28mV

The LF section is more complex. Two voltages must add to give 28mV. The voltage across R90 and R91 is each to be nominally 14mV.  
(e.g. the respective voltages might actually be 12mV and 16mV).

Mk. I module:	TP3-TP7 + TP4-TP8	Sum = 28mV
Mk. II module:	TP5-TP2 + TP6-TP2	Sum = 28mV

Similarly, on the negative supply side, the voltages are nominally -14mV. This should be easy to understand on examining the circuit diagram.

Mk. I module:	TP5-TP8 + TP6-TP8	Sum = 28mV
Mk. II module:	TP3-TP1 + TP4-TP1	Sum = 28mV

If all is well replace the fuses with spiral wound T3.15A type.

## **Verifying Frequency Response**

Measure the frequency response at the output terminals. The gain switch should be set to +4, and the trim pots first set to maximum. The generator signal should be -10dBu.

First measure the LF output, which is presented to the bottom pin on the speaker connector. Make two runs: the first run with the LF trim pot set to +3dB (max), the second with the pot set to -3dB (min). Measure the HF output next (top speaker pin), again make two runs: first run with the HF trim pot set to +3dB (max) second set to -3dB (min).

The output should be within +/-1 dB of the values shown below:

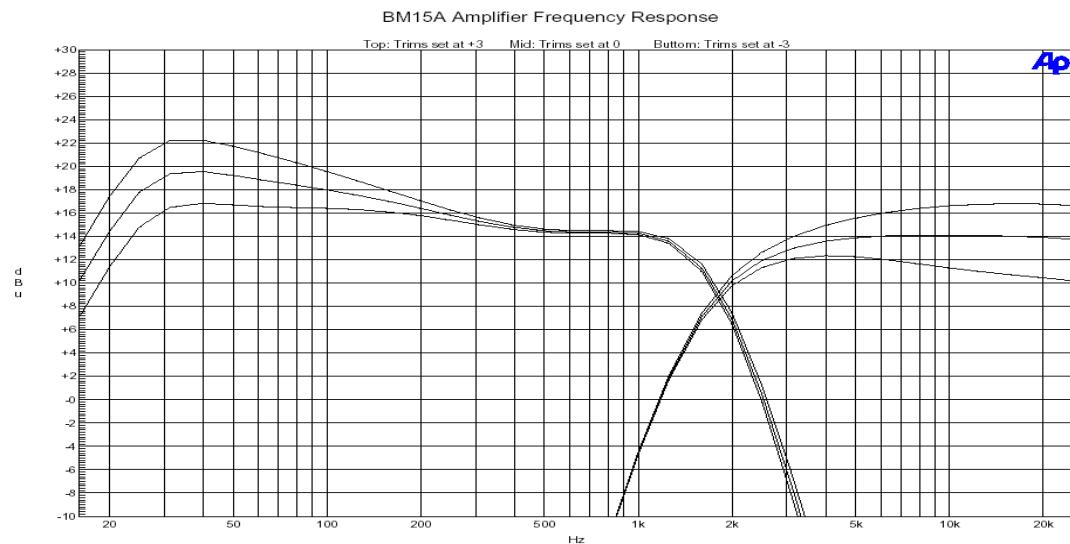

Figure 2: Amplifier Frequency Response, Input: -10dBu

LF Amp. Freq	trim -3 dBu	trim +3 dBu	HF Amp. Freq	trim -3 dBu	trim +3 dBu
