SPECIFICATIONS

Main Amplifier Section

Circuitry configuration All stages Direct coupled.
DC servo circuit.

Actual power output Sine wave output,
both channels driven, 20Hz – 20kHz
70W + 70W (8 ohms)
140W + 140W (4 ohms)

THD Less than 0.003% (actual power output)

IM Distortion Less than 0.003% (actual power output)

Frequency Response 5Hz – 300kHz

Input Sensitivity/Impedance 1.23V/20k ohms

Preamplifier Section

Circuitry Configuration All stages Direct coupled
DC servo circuit

Input (Level/Impedance)

Tuner 150mV/20k ohms

Tape (1, 2) 150mV/20k ohms

CD 150mV/20k ohms

AUX (1, 2) 150mV/20k ohms

Outputs (Level/Impedance) . . Pre output 1.23V/600 ohms

S/N Ratio

PHONO 90dB (-142dBV)

TUNER 110dB (-126dBV)

TAPE (1, 2) 110dB (-126dBV)

CD 110dB (-126dBV)

AUX (1, 2) 110dB (-126dBV)

RIAA Deviation Within ±0.2dB (10Hz – 100kHz)

PHONO Overload More than 300mV

Subsonic Filter 15Hz (-3dB, 6dB/Oct)

Input/Output Phase Inphase

Power Supply Section and Others

Circuitry Configuration Stage independent
shunt regulator + reserve power supply

Power Requirement

BU Only AC 120V, 60Hz

BS Only AC 220V, 50Hz

Power Consumption 270W, 550 VA

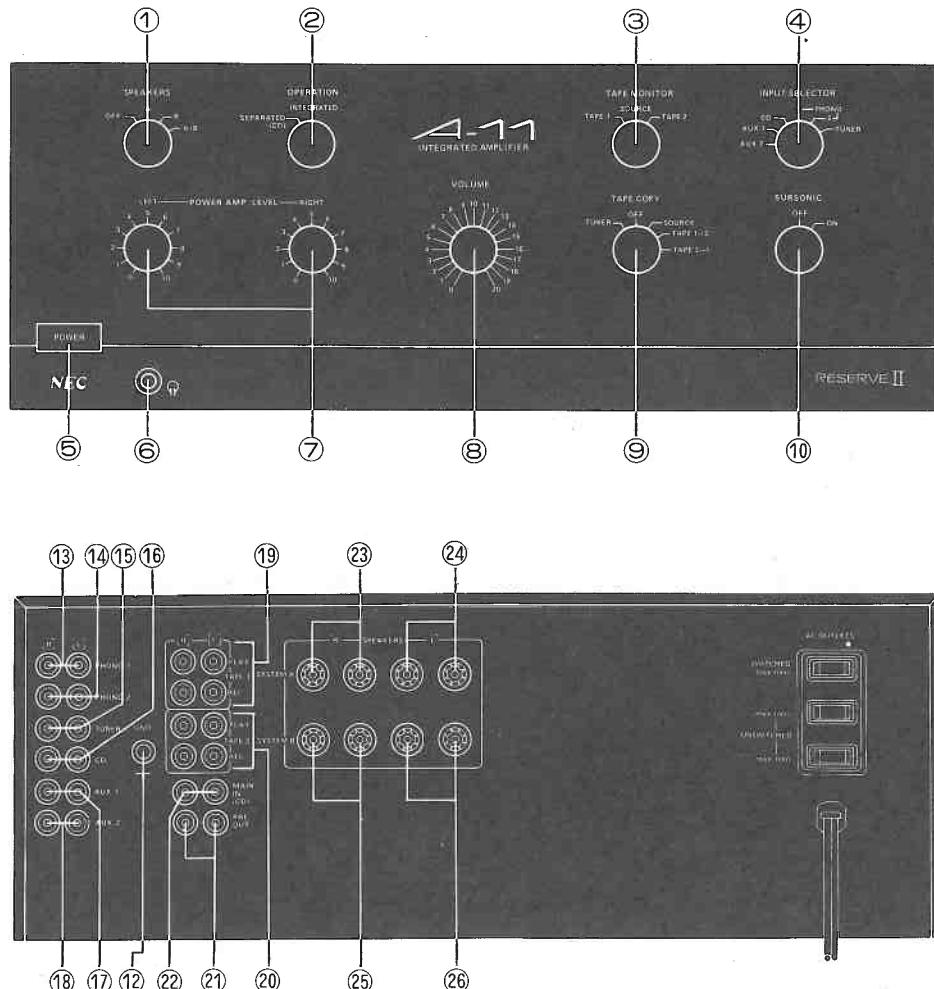

External dimensions 430 (W) x 150 (H) x 430 (D) mm

Weight 22kg

NEC Corporation

TOKYO, JAPAN

Control Operation

1. SPEAKER Switch

This allows two pairs of speakers to be turned on and off. Position A will produce sound from the speakers connected to the SPEAKERS SYSTEM-A terminals (23) and (24), and position B will produce sound from the speakers connected to the SPEAKERS SYSTEM-B terminals (25) and (26).

Position A + B will produce sound from both speaker pairs A and B. When operating two pairs of speakers, using position A + B, the impedance rating of each speaker used should be in excess of 8 ohms. No sound will be heard at the OFF position setting. Set the SPEAKERS switch to the OFF position when only using a pair of headphones.

2. OPERATION Switch

Use this switch when using the A-11 as part of a multi-amplifier system, or when using the pre amplifier and power amplifier section independently, for example with an external signal processor such as a graphic equalizer connected between. Normally this switch should be set to the INTEGRATED position.

3. TAPE MONITOR Switch

This switch is used for listening to tape decks connected to the TAPE 1 terminals (19) and TAPE 2 terminals (20), or for simultaneous recording monitoring of a three-head tape deck. This switch can also be used with an external signal processor, such as a graphic equalizer. Set this switch to SOURCE when listening to program sources selected with the INPUT SELECTOR switch (4).

Connection Cord

4. INPUT SELECTOR Switch

Set this switch to the position corresponding to the desired program source.

TUNER: This selects the tuner program source.

PHONO 1, 2: This selects the record player program source connected to the PHONO terminals (13), (14).

CD: This selects the digital compact disc player program source.

AUX 1, 2: This selects the program source connected to the AUX terminals (18), (19).

5. POWER Switch

This switch turns the power on and off. The MUTE function will prevent any sound from being heard for 8 – 9 seconds after the power is turned on.

6. HEADPHONE Jack

When listening through a pair of headphones, connect them to this jack.

7. POWER AMPLIFIER LEVEL Control

This control adjusts the sound output volume of the power amplifier section. It can be used to adjust the relative volume balance between right and left for the speakers and headphones, or for adjusting the output level when using the A-11 as a part of multi-amplifier system.

8. VOLUME Control

This control controls the sound output level from the speakers and headphones.

9. TAPE COPY Switch

This switch is used to select the recording source.

10. SUBSONIC FILTER Switch

When playing records at high listening levels, low frequency rumble caused by warped records can be irritating to you and damaging to your speaker system. Turning on the SUBSONIC FILTER switch (10) will eliminate the low frequency rumble.

- Make sure that the power is turned off before attempting to make any connections.
- Be sure not to short-circuit the speaker terminals.
- Be sure to properly observe left and right when making unit connections.
- Be sure that each power and connection plug is inserted firmly.

Unit Connections

Using the Convenience AC Outlets

The amplifier is equipped with convenience AC outlets for supplying power to a tuner, record player, tape decks etc. The SWITCHED AC outlet will supply power to the unit connected only when the main power switch of the amplifier is turned on. The A-11 is also equipped with two UNSWITCHED AC outlets that will supply power independently of the main power switch.

- The power consumption of each unit connected to the convenience AC outlets should not exceed 100W.

Connecting a Speaker System

As shown in the above diagram, connect the right hand (R channel) speaker to the right hand speaker terminals on the amplifier, and the left hand speaker (L channel) to the left hand speaker terminals. The speaker terminals have plus (+: red) and minus (-: black) polarity, corresponding to the terminals of your speakers.

Normally, connect the plus terminals of the speaker to the plus terminals of the amplifier, and the minus terminals of the speaker to the minus terminals of the amplifier. However, some speaker systems will give better results when connected using reverse polarity; that is, connecting the plus terminals of the speaker to the minus terminals of the amplifier.

Connecting a Record Player

Please connect the left (L) channel and the right (R) channels to the corresponding PHONO terminals (13) and (14). Connect the ground wire of the record player to the ground (GND) terminal (12).

• MC cartridges

MC cartridges have a wide range of output levels, ranging from low ($50\mu\text{V}$) to high (2.5 mV) levels. Refer to the specifications sheet of your MC cartridge and connect the cartridge to the A-11E as follows.

For MC cartridges with a normal output level range, i.e. between $50\mu\text{V}$ (0.05mV) and $800\mu\text{V}$ (0.8mV), first connect the cartridge output to a booster transformer or an MC head amplifier and then connect that output to the PHONO terminals. Connect cartridges that have an output in excess of $800\mu\text{V}$ (0.8mV) or that have a built-in booster transformer, directly to the PHONO terminals.

Connecting a Digital Compact Disc Player

Connect the output terminals of the digital compact disc player to the CD (compact disc) terminals (16) or to the MAIN IN (CD) terminals (22) of the A-11E.

Connecting a Tuner

Connect the output terminals of the tuner to the TUNER terminals (15).

Connecting Tape Decks (Open Reel and Cassette)

Two tape decks can be connected and used. Connect the LINE INPUT terminals of the tape deck to the REC terminals of the amplifier's TAPE 1 terminals (19) or TAPE 2 terminals (20). Connect the LINE OUTPUT terminals of the tape deck to the PLAY terminals.

Connections to the AUX Terminals

These terminals are the auxiliary input terminals. When using a second tuner or digital program sources such as PCM processors, connect such components to the AUX terminals (17) and (18).

Connections to the PRE OUT and MAIN IN Terminals

Use these terminals when using an external signal processor such as a graphic equalizer or when using the A-11 as a part of a multi-amplifier system. Connect the PRE OUT terminals (21) to the input terminals of the graphic equalizer or channel divider, and connect the MAIN IN terminals (22) to the output terminals of the graphic equalizer or channel divider.

Using the OPERATION Switch

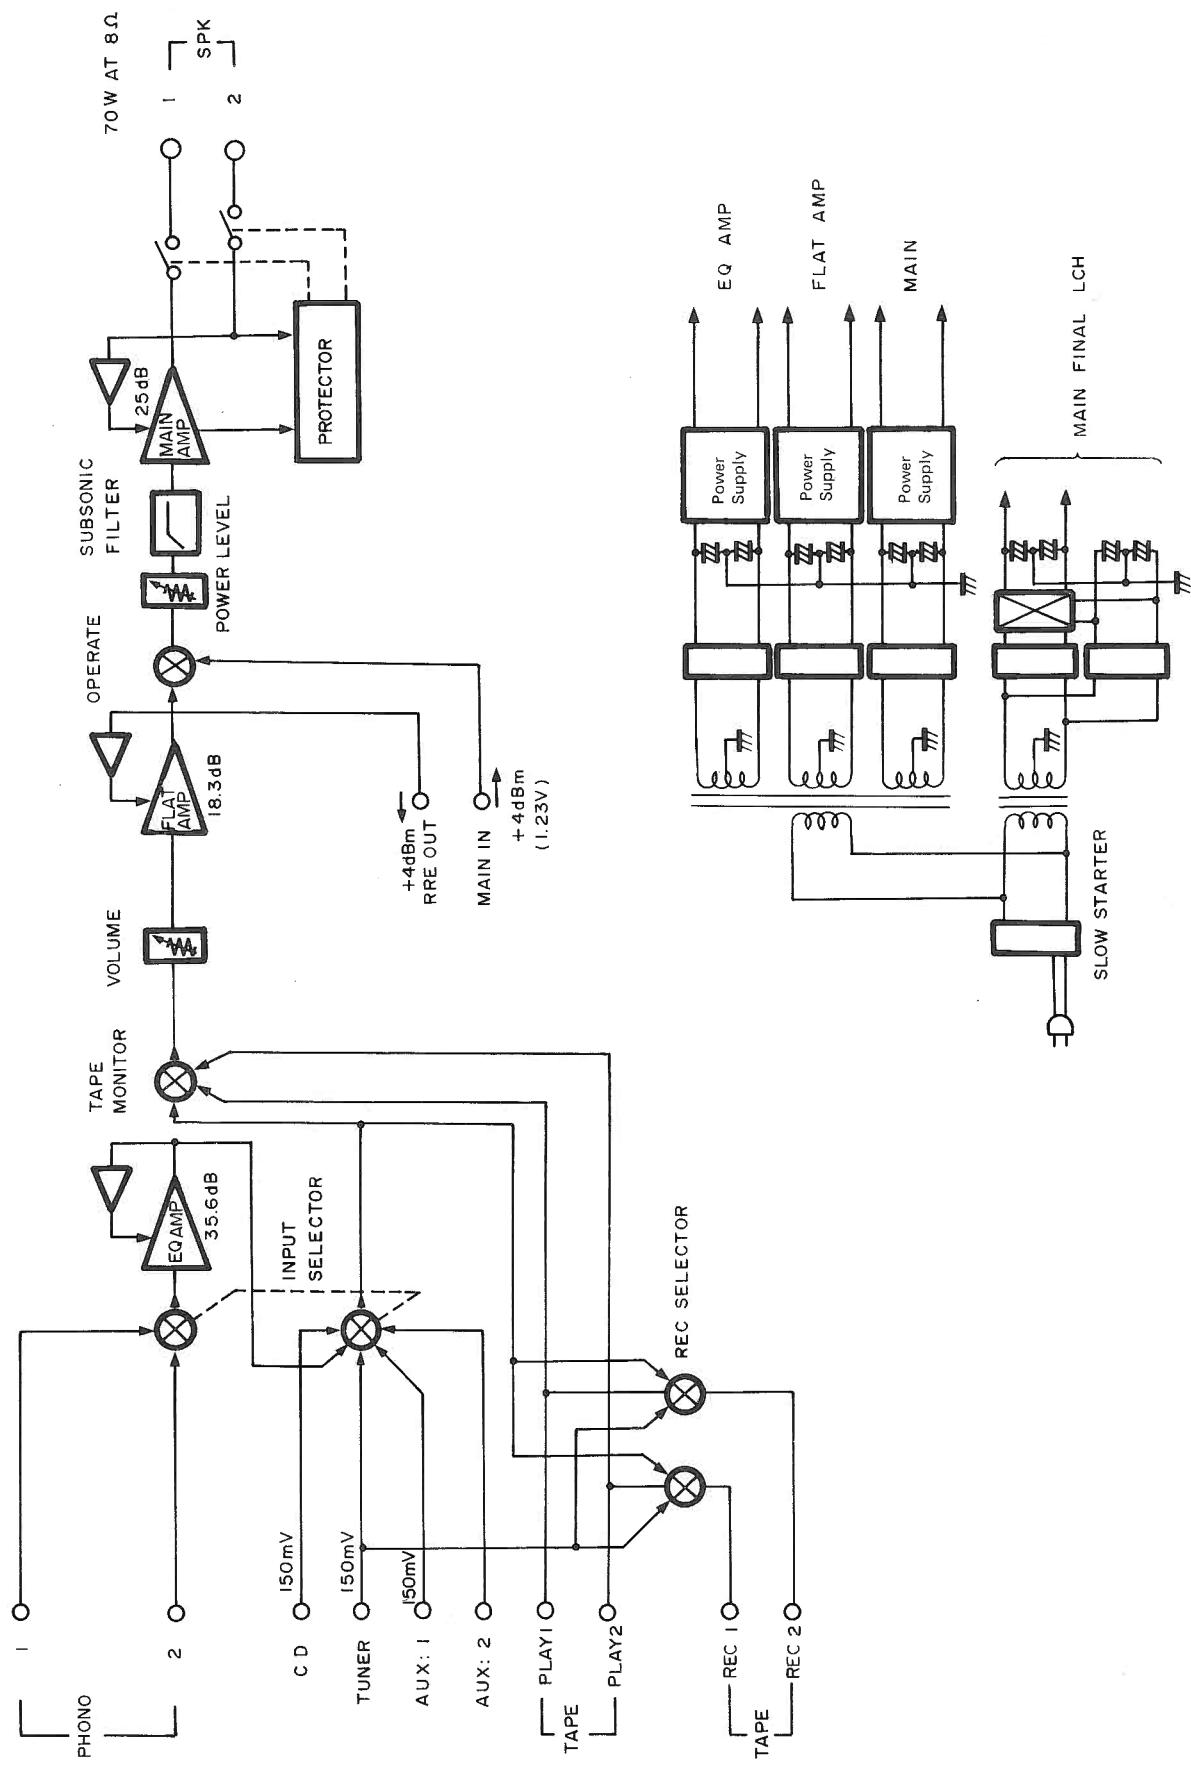

This switch selects between normal integrated operation of the pre amplifier and main amplifier stages, and separate operation of the pre amplifier and main amplifier stages. The latter position is for use with external signal processors such as graphic equalizers, or when using the A-11 as a part of a multi-amplifier system.

■ INTEGRATED: This position selects operation as a normal integrated amplifier. Since a pre amplifier output signal is being output from the PRE OUT terminals (21), this can be used to drive another main amplifier in parallel to the main amplifier stage of the A-11.

■ SEPARATED: The input of the main amplifier stage will be separated from the pre amplifier output. The signal input from the MAIN IN terminals (22) will be controlled by the POWER AMPLIFIER LEVEL controls (7) and then routed to the main amplifier stage.

Set the OPERATION switch to the SEPARATED position for use with external signal processors such as graphic equalizers, or when using the A-11 as a part of a multi-amplifier system.

Block Diagram

Disassembly Instructions

1. Removal of Top Cover

Remove screws (C1) and (C2) and pull the cover off as shown in Fig. 1.

(Note: Be careful not to disturb the wiring.)

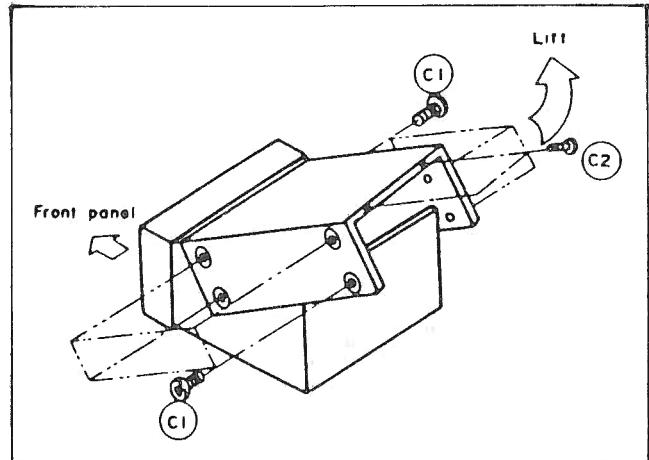

Fig. 1

2. Removal of Front Panel

Use a wrench (1.45 mm) to remove the 9 knobs on the front panel. Then remove the 5 nuts fastening the VR and front panel. After removing the power switch board (kept in place by claws), the front panel can be separated.

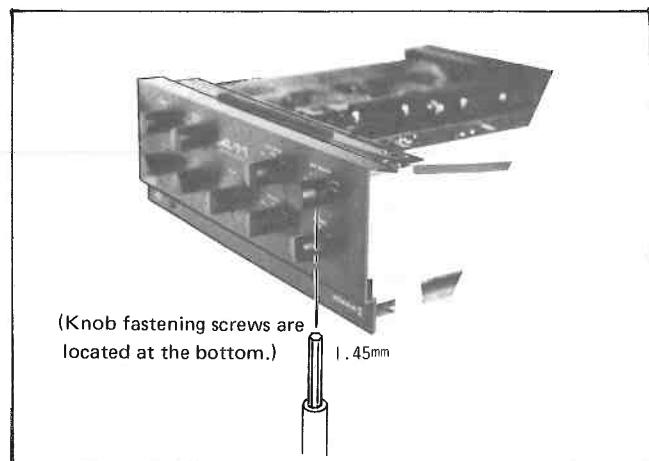

Fig. 2

3. Removal of VRs and Switches

Remove screws (F1) and remove the front top board. After removing the fastening nuts of the VRs and switches, these parts can be separated from the front panel.

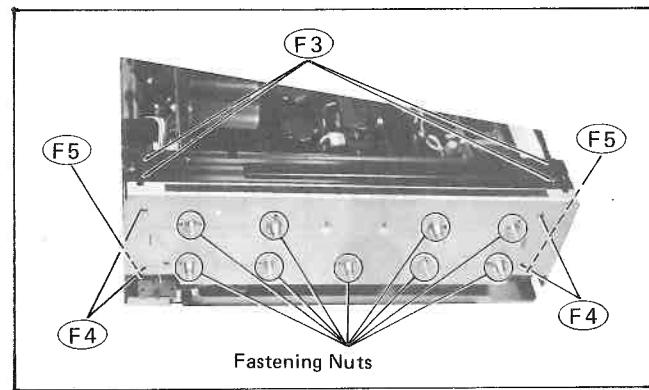

Fig. 3

4. Removal of Preamp Block

When screws (F2), (R1), and (S1) are removed, the EQ and flat amp boards can be removed. (Loosen the wiring, referring to the wiring diagram.)

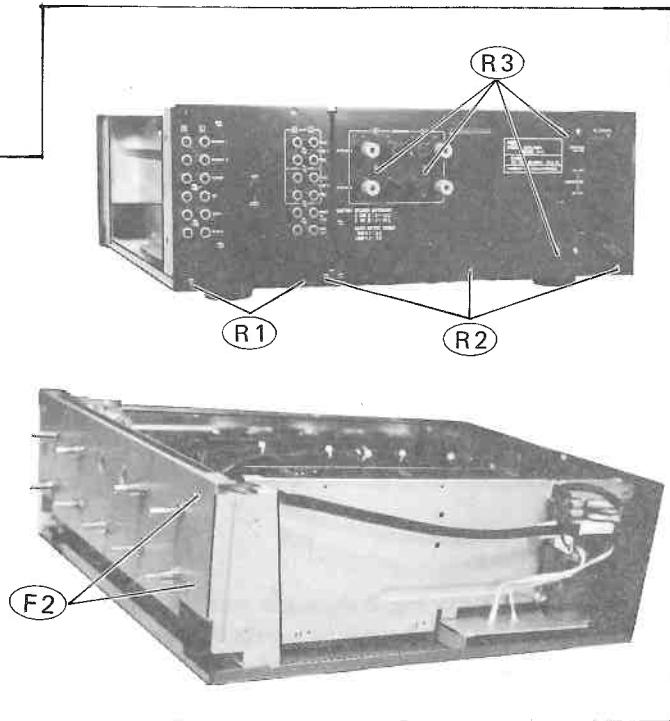

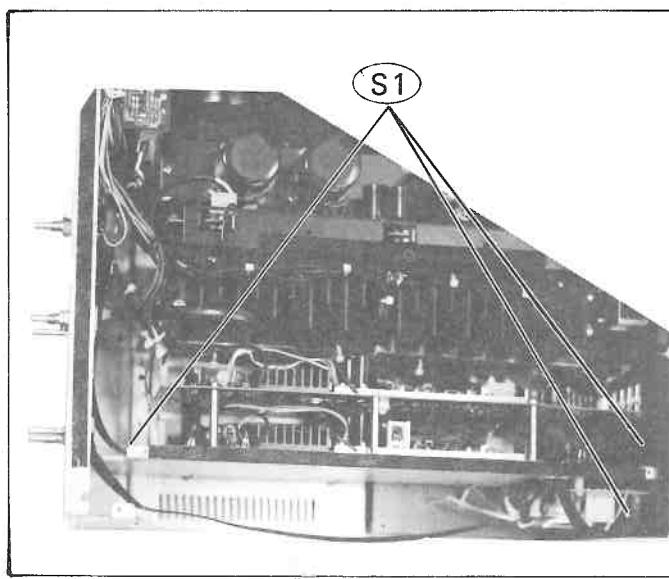

Fig. 4

5. Removal of EQ and Flat Amp PWBs

After removing screws (E1) and desoldering the solder connections the EQ and flat amp PWBs, the two boards can be removed.

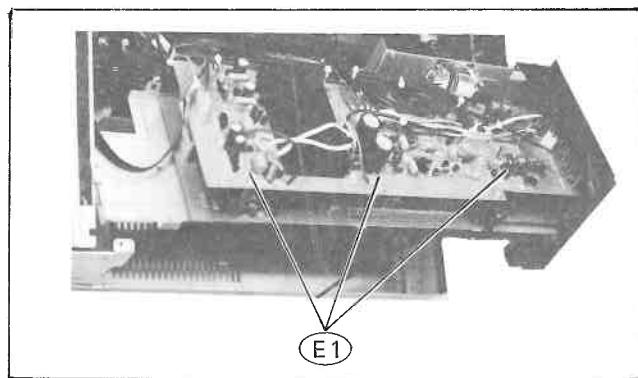

Fig. 5

6. Removal of Front Chassis

When (F4) and (F5) shown in Fig. 3 are removed, the front chassis can be removed. The PWBS fastened to the front chassis can be separated after removing the respective, VRs, switches, and screws.

7. Removal of Main Block

Remove the front chassis and screws (M1) and (R2). After detaching the headphone jack from the chassis, the main block can be removed.

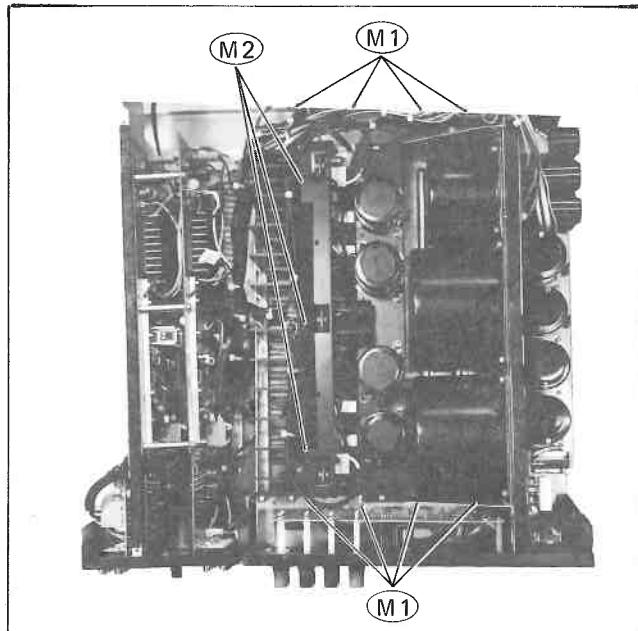

Fig. 6

8. Removal of Main (V) PWB (PWB Standing on Heatsink)

Remove screws (M2) and desolder (TR). The main (V) PWB can now be removed.

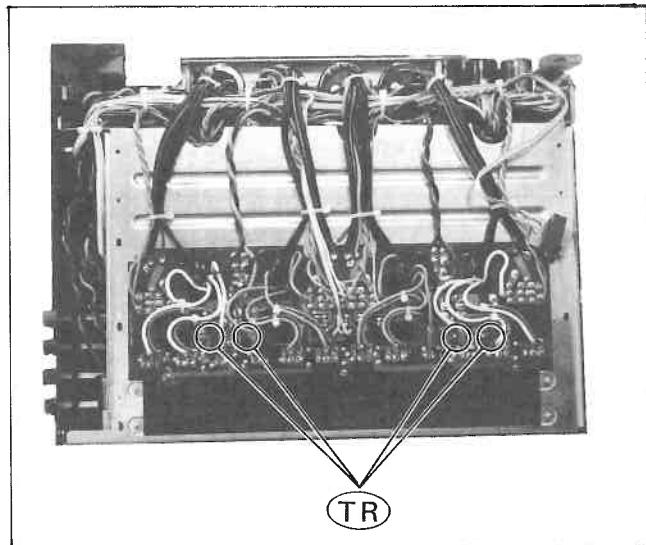

Fig. 7

9. Removal of Protector PWB

After removing screws (R3) shown in Fig. 4, the protector PWB can be removed from the rear panel.

10. Wiring Check

The shaded sections in Fig. 8 show the routing pattern for the internal wiring. As the wiring layout has considerable bearing on S/N ratio, restore the original conditions as closely as possible.

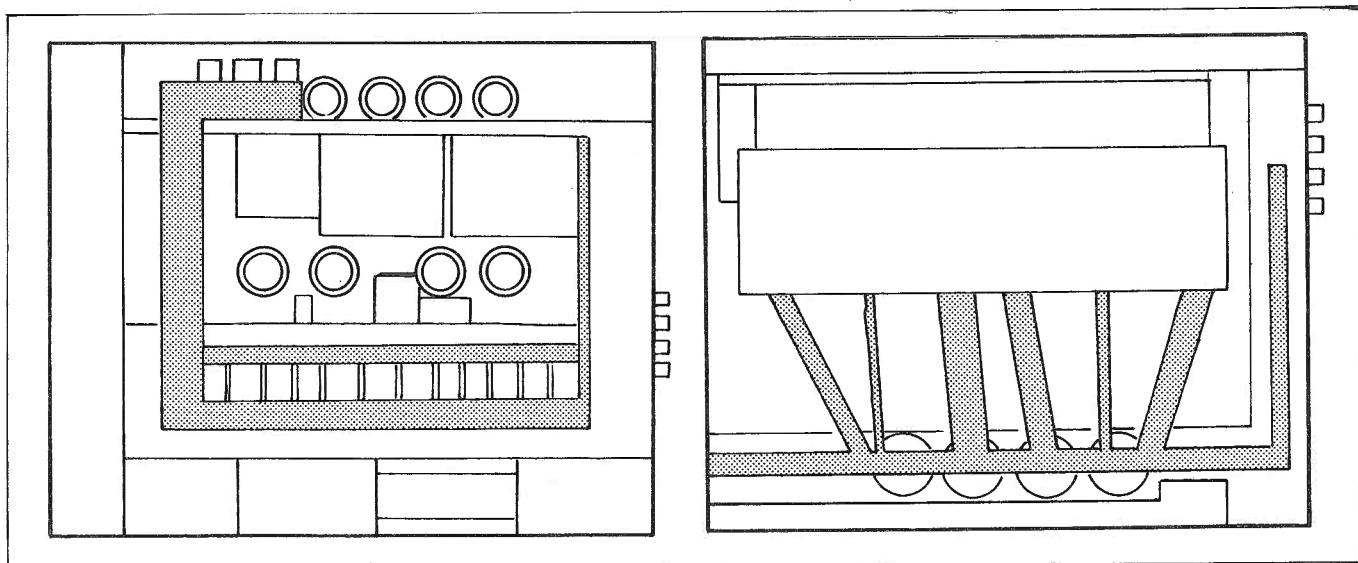

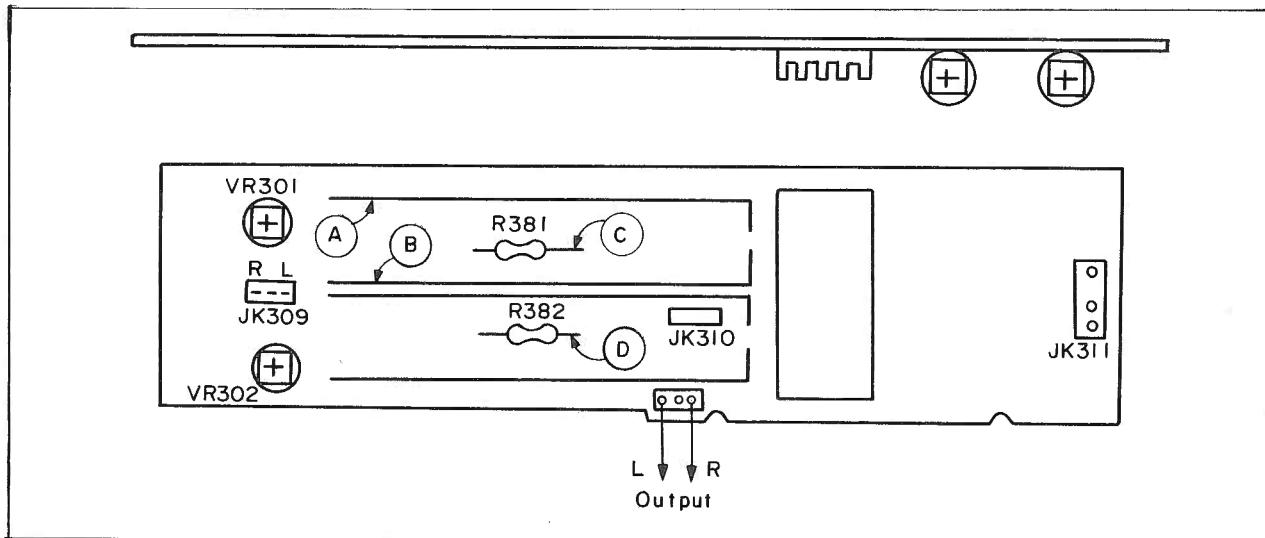

Fig. 8

Adjustments

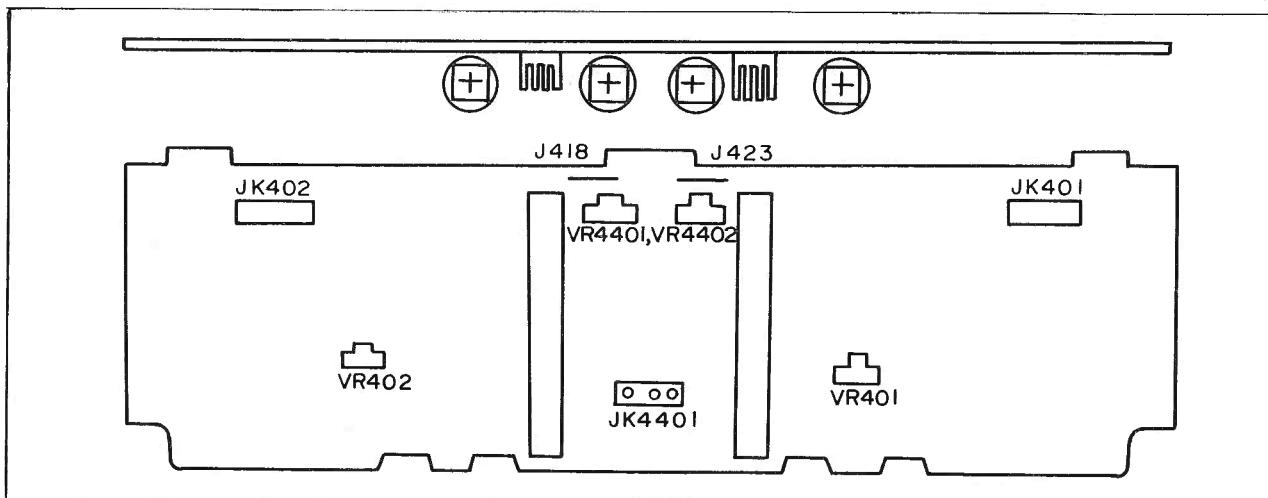

1. EQ & Flat Amp Adjustment

- (1) Adjust VR301 to obtain a voltage of less than $\pm 0.5\text{mV}$ between the (C) terminal of R381 and ground.
- (2) Adjust VR302 to obtain a voltage of less than $\pm 0.5\text{mV}$ between the (D) terminal of R382 and ground.

2. Adjustment of Main Amplifier

- (1) Adjust VR4401 to obtain a voltage of +55V between J423 and ground.
- (2) Adjust VR4402 to obtain a voltage of -55V between J418 and ground.
- (3) Provide a speaker load of 8 ohms, apply a 20kHz signal to the input to obtain maximum output. Observe the output waveform and residual distortion waveform on an oscilloscope.
- (4) After two minutes, adjust VR401 and VR402 to obtain minimum distortion and eliminate switching distortion from the residual distortion waveform.
- (5) Reduce the input signal to zero and make certain that the voltages across R519 and R520 are above 15mV and below 18mV DC. If not, adjust VR401 and VR402. (Remove the sub bottom board for R519 and R520).

Purpose of Each Circuit

1. EQ Amplifier Circuit

The amplitude vs. frequency characteristic commonly used for cutting LP records is shown in Fig. 9. When this is traced by ordinary MM or MC cartridges, low-frequency sounds gradually diminish in level, and high-frequency sounds increase in level vs. the center frequency of 1kHz. Overall output level therefore is low, and the sound balance, if reproduced in this way by the loudspeakers, would be extremely unnatural, with overbright treble and weak bass. For this reason, the amplifying characteristics of the equalizer stage are chosen to provide exactly opposite conditions from the cutting process. Around a center frequency of 1kHz, amplification of lower frequencies is emphasized and that of higher frequencies reduced (resulting in the so-called RIAA curve). In this way, a compensation of the cartridge output characteristics is achieved, as shown in Fig. 11, and the overall output characteristics of this stage are flat, equivalent to the original signal characteristics before the phono recording process.

As the EQ amplifier has the highest gain of all stages in the preamplifier, high S/N ratio is also essential.

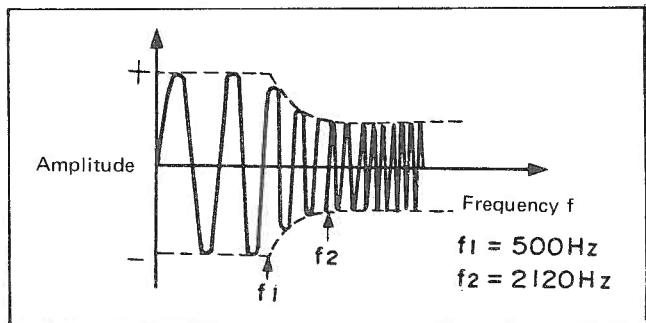

Fig. 9

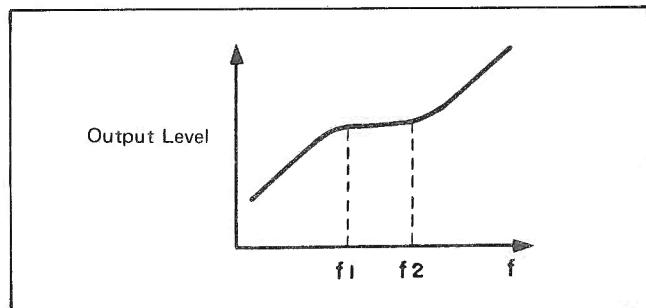

Fig. 10

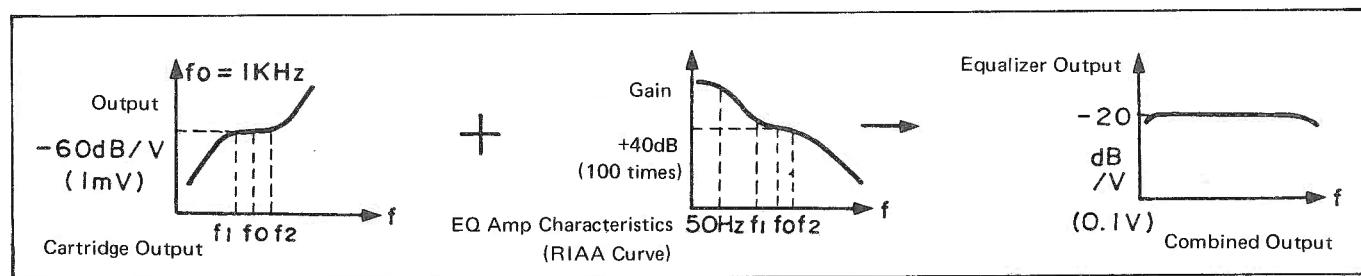

Fig. 11

2. Flat Amplifier Circuit

The output signals from the EQ amplifier stage and from the tuner and tape inputs are in turn sent to the power amp level control and subsonic filter stages. But as these stages introduce a certain gain loss, it is necessary to first pass the signals through an amplifying stage with flat frequency response characteristics, to prevent losses. This task is fulfilled by the flat amplifier stage, which is provided before the power amp control and subsonic filter.

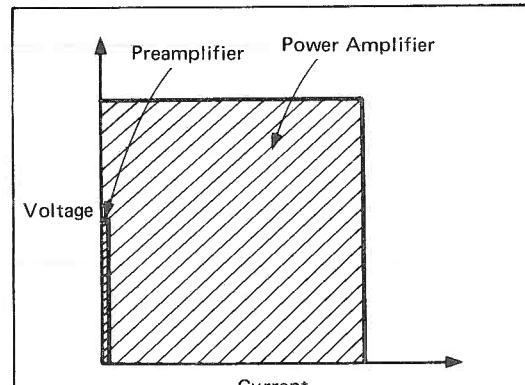

Fig. 12

3. Main Amplifier Circuit

Although the signal has undergone some amplification in the EQ and flat amplifier stages, it is still much too small to directly drive the loudspeakers. (Compare Fig. 12) The main amplifier provides power amplification to step up the signal to sufficiently high voltage and to a level where it can sustain the large currents required to drive the loudspeakers. The main amplifier circuit consists of 4 blocks, as shown in Fig. 13.

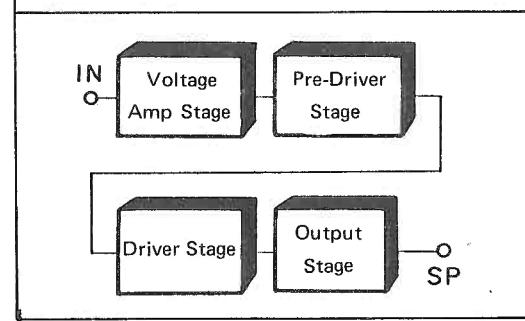

Fig. 13

■ Voltage Amplification Stage

This stage steps up the voltage of the input signal, thereby increasing the gain of the power amplifier. It also serves to combine the NFB signal and the input signal.

■ Pre-Driver Stage

Serves to supply a large signal to the driver and output stages.

■ Driver Stage, Output Stage

The purpose of the driver stage is to drive the final output stage. These two stages provide current amplification of the voltage supplied by the voltage amplification and pre-driver stages and apply this current to the loudspeakers.

4. Protector Circuit

The presence of a DC current in the output, due to a defect in the power amplifier or the like, would cause damage to the loudspeakers. On the other hand, a short-circuit in the speaker terminals would result in excessive current flows and destruction of the output stage. The protector circuit serves to prevent such occurrences by providing the following functions.

- Shut off the current to the amplifier and speakers if abnormal operating conditions are detected.
- Prevent the occurrence of shock noise when the power is switched on and off (muting function).
- Revert to normal operation when the abnormal condition has ceased.

5. Power Supply Circuit

The sound quality of an integrated amplifier depends to a great deal on its power supply. As can be seen from Fig. 14, the input level of the EQ amp is about 1/10000 (-80dB) as compared to the power amplifier's output level. If the power supply of the EQ amp, for example, introduces noise, this noise will appear in the speaker output amplified by about 100 times (40dB). To preclude this possibility, the A-11E employs one transformer (PT003) for the EQ amp, flat amp and main (V) amp, and separate transformers (PT001, PT002) for the main (P) amp.

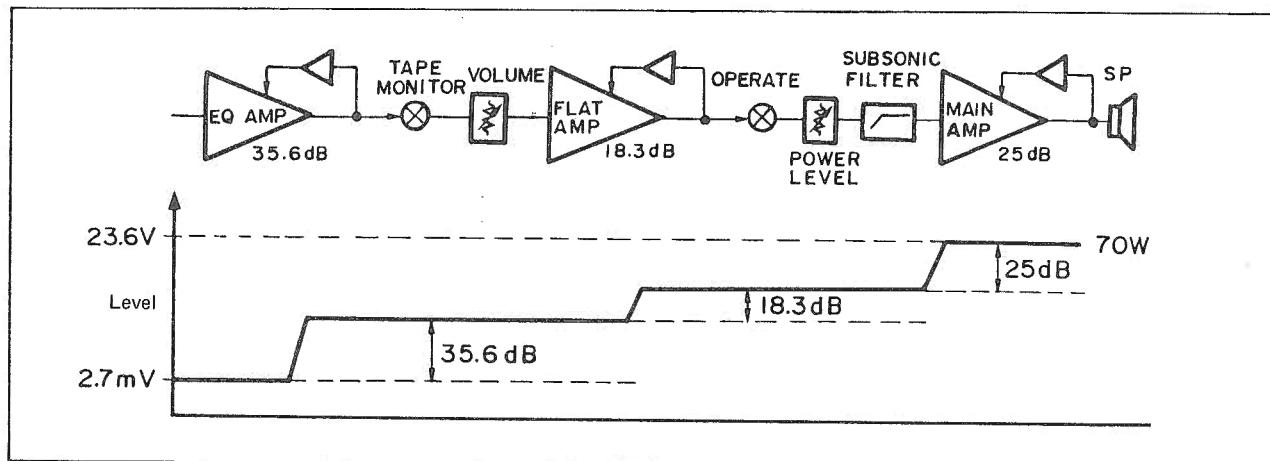

Fig. 14

Circuit Description

<EQ Amplifier Circuit>

1. Cascade Configuration (Fig. 15, 16)

In an ordinary emitter follower circuit, a feedback capacity arises between the transistor's base and collector, and a floating capacity between the collector and ground, as shown in Fig. 15. These unwanted capacities cause high-frequency distortion and impair amplifier linearity. A solution to this problem is shown in Fig. 16. Transistors TR301 and TR303 are connected in series, and the base of TR303 is grounded. This is called cascade configuration, which is largely immune to the effects of feedback or floating capacity.

When an input is applied to TR301, a current flows between the drain and source. Thereby current amplification, but not voltage amplification is achieved. TR303 on the other hand, due to its characteristics as a base follower circuit, causes almost no current amplification, but operates approximately like an emitter follower circuit, providing voltage amplification.

2. Differential Input Type Equalizer Circuit (Fig. 17)

TR305 and TR307 are transistors of identical characteristics (2SC1845), and their emitters are connected to a common constant-current supply. Therefore the sum I_0 of the collector currents I_{C1} (TR305) and I_{C2} (TR307) is always constant. If the base current of TR305 is at a positive potential vs. TR307, I_{C1} increases, and accordingly I_{C2} decreases, as I_0 is constant. This means that a current differential occurs between the collectors of TR305 and TR307, and gain is introduced. If on the other hand the base potential of TR305 and TR307 changes simultaneously by the same value, the collector currents of both transistors do not change and there is no alteration of collector voltage, as I_0 is constant. Thus a differential circuit produces no output with in-phase signals. In-phase components are therefore extracted from the input signal. When feedback voltage is high, the output decreases, and when feedback voltage is low, the output increases. The capacity to suppress in-phase components effectively protects the circuit against external influences such as power supply hum, temperature changes, etc.

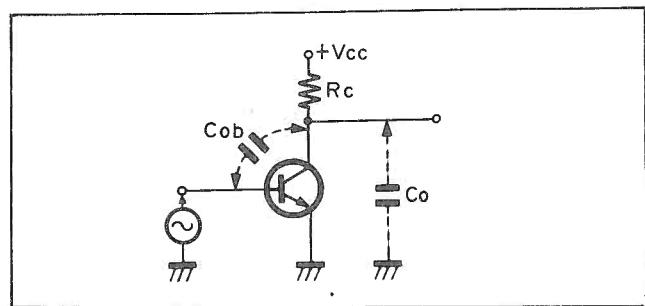

Fig. 15

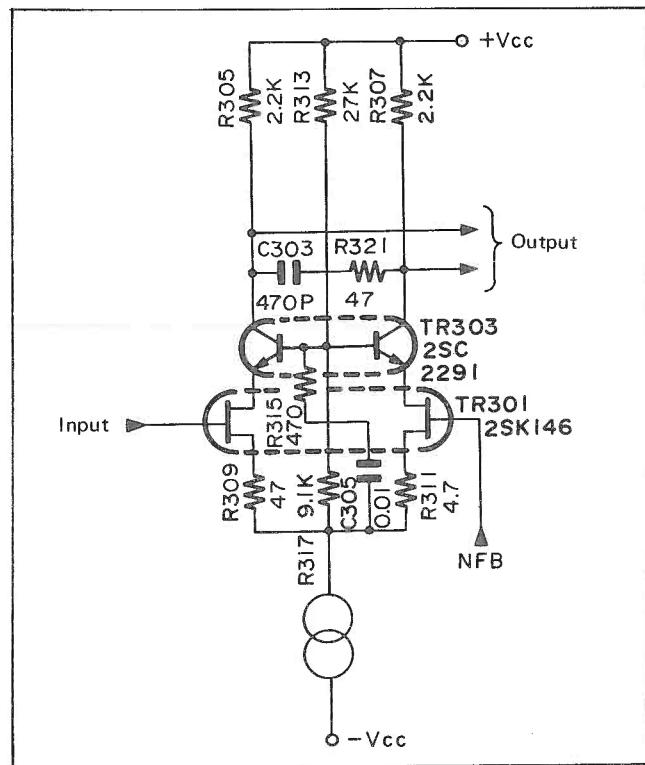

Fig. 16

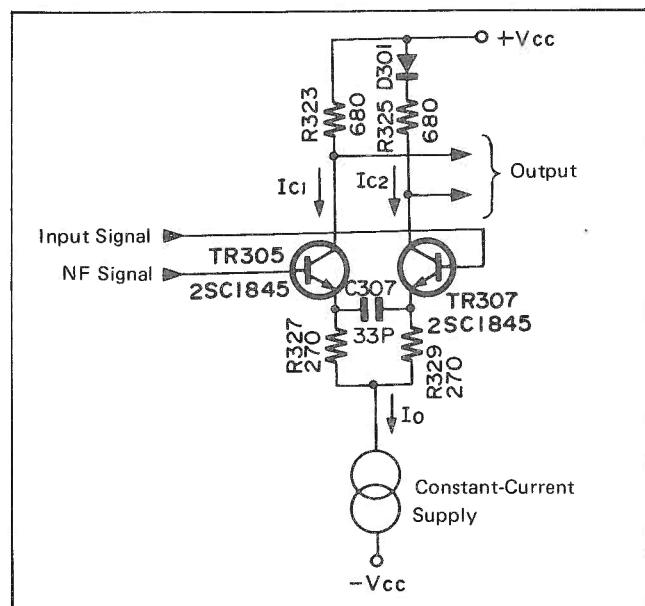

Fig. 17

3. Current Mirror Circuit

The circuit configuration shown in Fig. 18, consisting of TR309, D301, R325, R339, and R341 is called a current mirror circuit. The circuit is determined by identical conditions for the base/emitter of TR309, D301 and the values of R325, R339, and R341. Therefore, if a current flows in the collector of TR307, an exactly opposite collector

current flows in TR309 and D301. This signal is amplified by the cascade-configuration circuit consisting of TR311, TR315, R315, D305, C313, TR317, TR313, R347, D307 and C315. Then it is supplied to the SEEP circuit explained below.

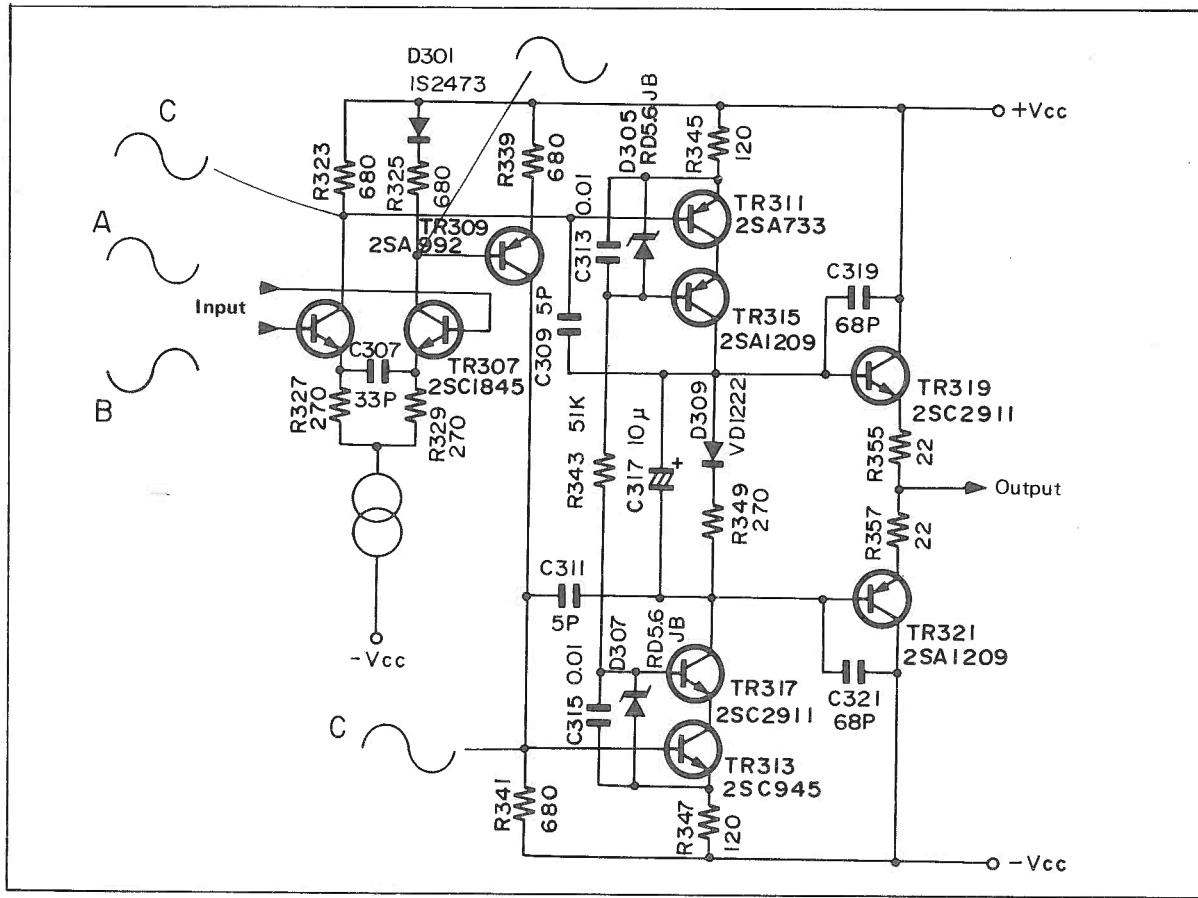

Fig. 18

4. SEEP Output Type Equalizer Circuit

When signals A and B are applied to the input of the circuit shown in Fig. 18, signal C appears at the bases of TR311 and TR313. Fig. 19 shows a simplified SEEP type equalizer amp circuit. A forward bias current is applied to the bases of TR319 and TR321, causing the transistors to be con-

stantly ON. When a signal such as C is applied to the input, TR319 produces the signal D and TR321 the signal E. The output therefore is the combined signal of D and E, which is the input signal (from the cartridge) amplified by approximately 60 times (35.5dB).

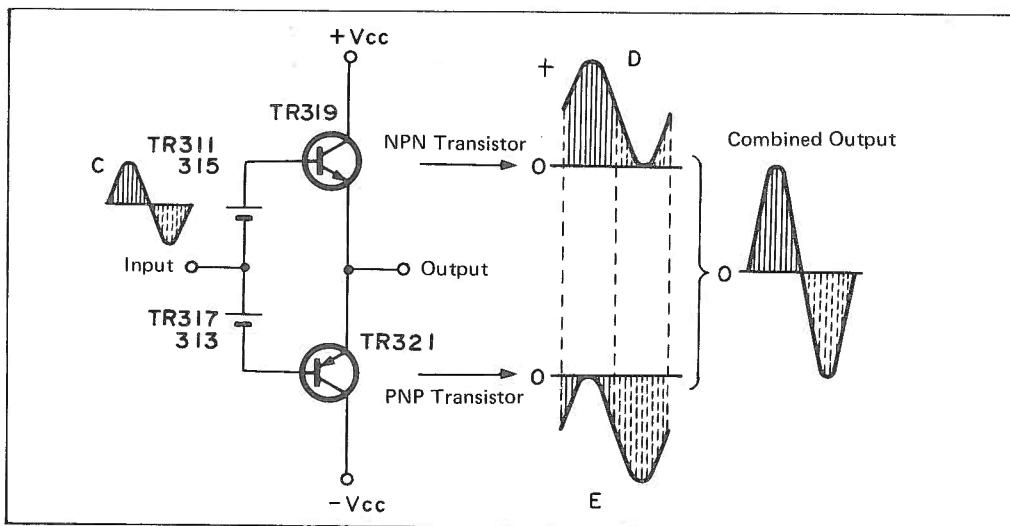

Fig. 19

5. NFB Circuit

Fig. 20 shows the negative feedback circuitry. I is the mixing (insertion) stage, II is the amplifier section, with input voltage and output voltage at opposite potential. III is the feedback loop (beta) through which the signal voltage appearing at the output of section II is feedback to the input. The characteristics of the NFB circuit are chosen in such a way that with sufficiently large feedback the overall amplification factor A becomes 1/beta, regardless of the amplifier section's amplification factor Av. Therefore, determining beta also results in determining the overall amplification factor A as a constant. This NFB circuit has the following effects:

- (1) Stabilization of amplification factor
- (2) Reduction of non-linear distortion
- (3) Improvement of frequency response
- (4) Improvement of S/N ratio
- (5) Control of input and output impedance, etc.

By giving the beta circuit a certain frequency response characteristic, the amplifier can be designed for a desired frequency response, which is used in the EQ amp for RIAA equalization. The A-11E employs the circuit shown in Fig. 21.

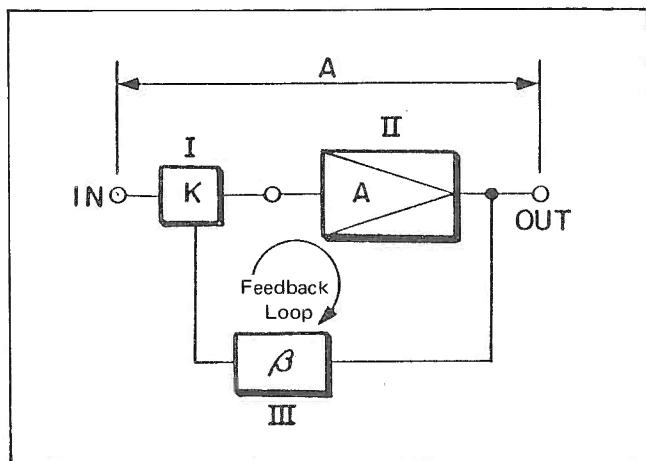

Fig. 20

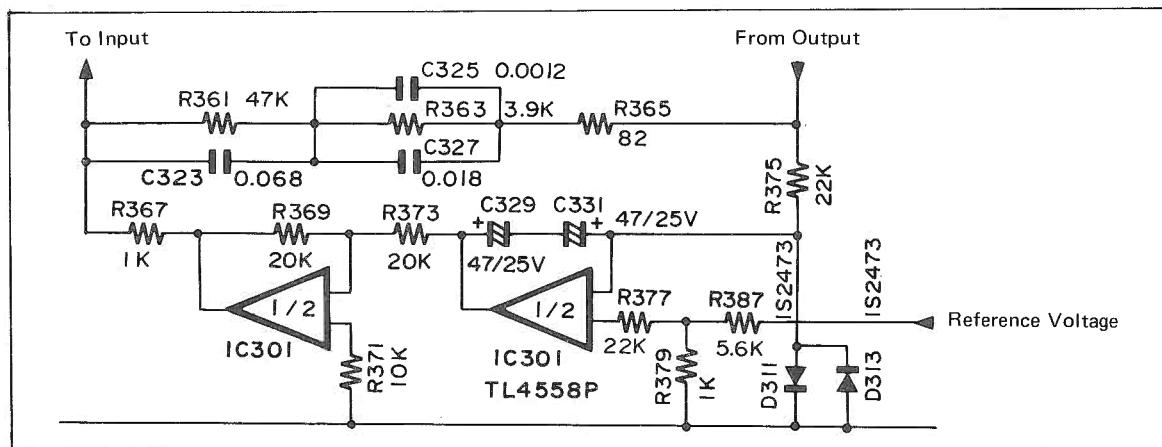

Fig. 21

5-1 RIAA Playback Equalization Circuit

The RIAA parameters require that the equalizer amplifier has a frequency response characteristic as shown in Fig. 22. When the compensation curve is converted into a straight line, as represented by the dotted line in the graph, it rises by 6dB per octave below 600Hz and falls by 6dB per octave above 2130Hz. The point where low-frequency boost sets in is called turnover frequency, and the point where high-frequency cut sets in the roll-off frequency. The RIAA compensation frequencies for the A-11E can be calculated as follow.

$$\text{therefore } f = \frac{1}{2\pi CR}$$

$$f_1 = \frac{1}{2\pi \times C_{323} \times R_{361}} = 49.8 \text{ [Hz]}$$

$$f_2 = \frac{1}{2\pi \times C_{323} \times R_{363}} = 600 \text{ [Hz]}$$

$$f_3 = \frac{1}{2\pi \times C_{327} \times R_{365}} = 2267.2 \text{ [Hz]}$$

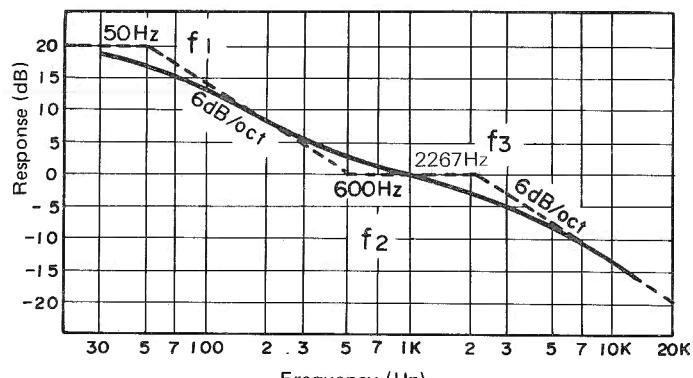

Fig. 22

This shows that at low levels feedback increases, as the impedance Z increases towards higher signal frequencies.

5-2 DC Servo Circuit

The DC servo circuit consists of the inverter amplifier IC301. The basic principle is shown in Fig. 23. the feedback amount ANF is calculated as follows.

$$ANF = \frac{XC}{R}$$

$$\text{follow } XC = \frac{1}{jWC}$$

$$ANF = \frac{\frac{1}{jWC}}{R}$$

$$\text{Therefore } = \frac{1}{jWCR}$$

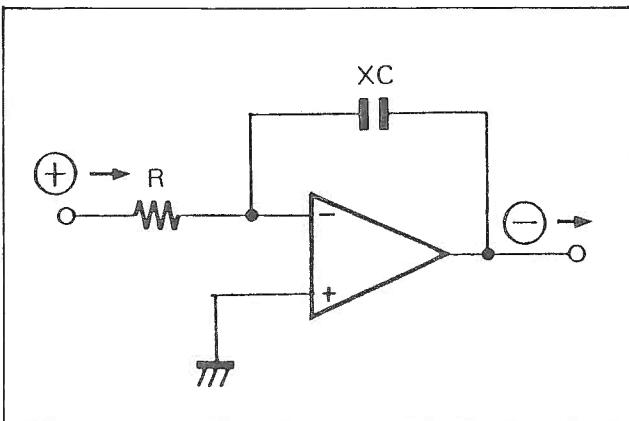

Fig. 23

This means that signals below the frequency determined by CR are cut off when applying negative feedback. Very low frequency signal can be considered equivalent to DC current. But on the other hand, the amplification factor in the low range is high, according to the RIAA characteristic

shown in Fig. 22. Therefore, given a response of 40dB, for example a signal of 0.05Hz appearing with 10mV at the input would appear at the output with 1V. For this reason, XC is employed in the feedback section to control very low frequency components (DC servo control).

<Flat Amplifier Circuit>

The flat amplifier circuit employs the same circuit configuration as the EQ amplifier, but without the RIAA compensation circuit.

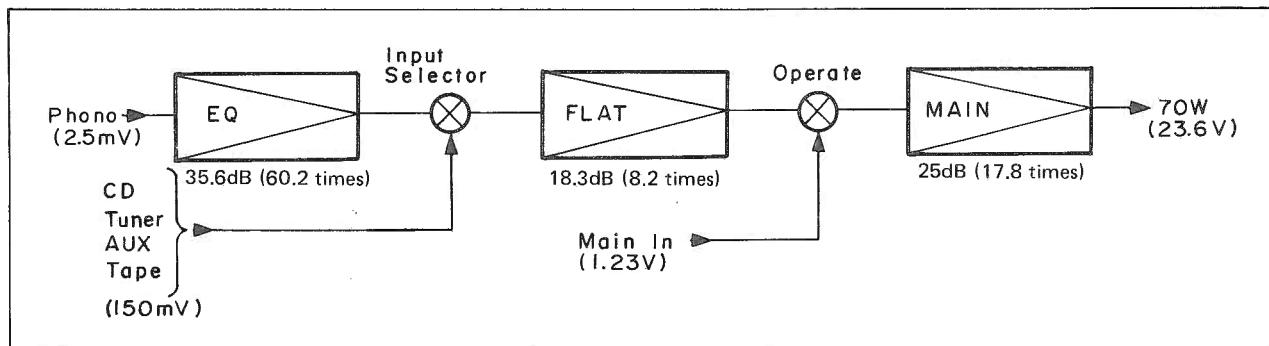

Fig. 24

Fig. 24 shows the gain for the various amplifying stages of the A-11E. The standard output level of ordinary Hi-Fi sources is 2.5mV for Phono, and 150mV for Tuner, Tape, etc. (The Phono level is increased to 150mV by the EQ amplifier.) The flat amplifier serves as a buffer stage to supply these signals to the high output impedance main amplifier without deterioration of output voltage, gain or frequency response characteristics.

<Main (V) Amplifier Circuit>

The purpose of the main (V) amplifier circuit is to provide voltage amplification. Fig. 25 shows the circuit configuration.

The operating principle at the various points is explained in the following.

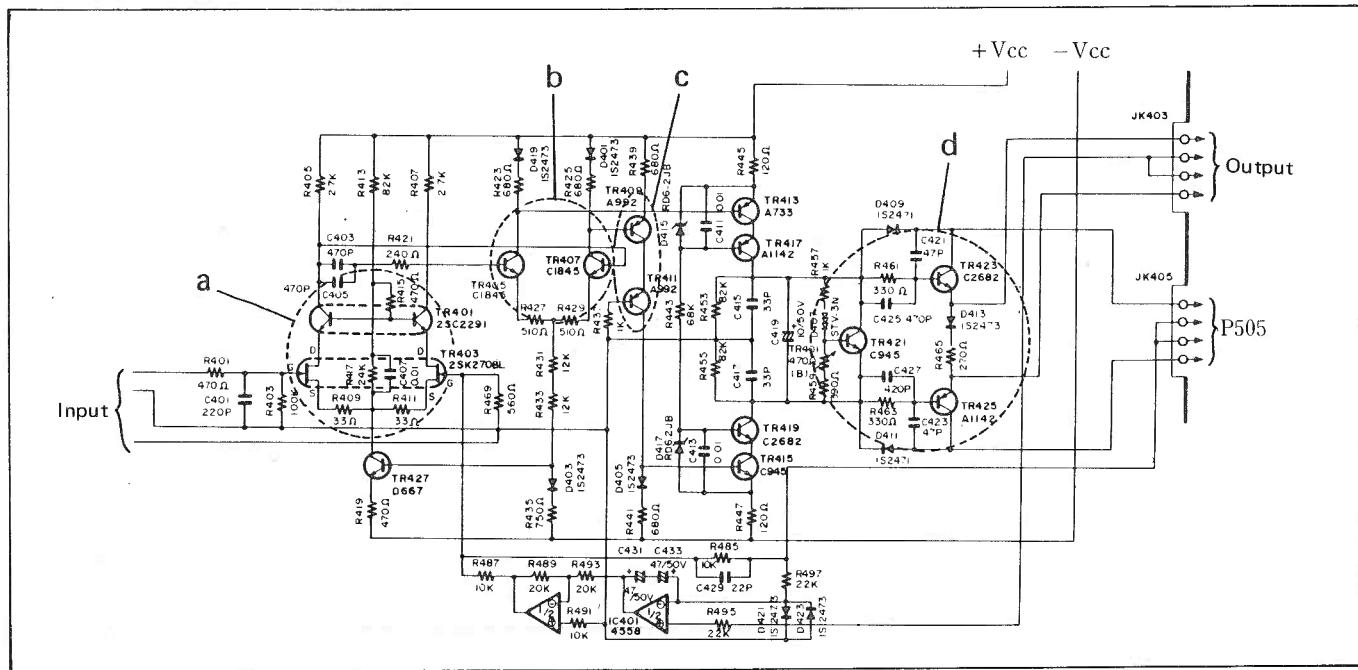

Fig. 25

1. Point a: Cascade connection for voltage amplification with minimum deterioration by feedback or floating capacitance.
2. Point b: Differential circuit configuration for voltage amplification with minimum susceptibility to external influences such as power supply hum, temperature changes, etc.
3. Point c: Current mirror circuit to induce an exactly opposite collector current from TR407 in TR411 and provide the input signal to the SEEP circuit.

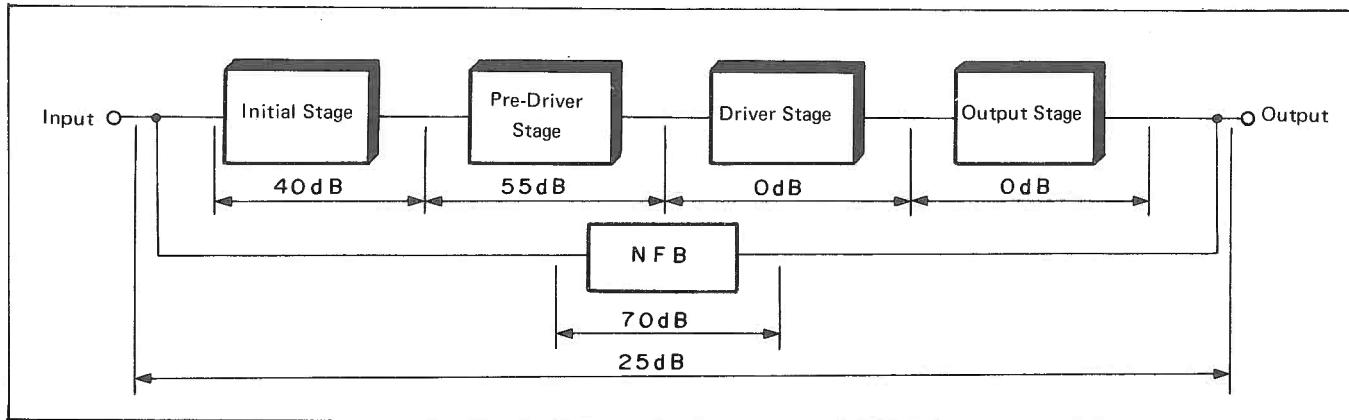

4. Point d: Pre-driver stage with cascade connection for voltage amplification with minimum deterioration by feedback or floating capacitance.

As the first stage of the main (V) amplifier (points a and b) serve mainly for impedance conversion and NFB connection, low-noise performance is essential and high gain cannot be achieved. On the other hand, the driver stage and output stage described below serve only for current amplification without voltage amplification. Therefore most of the gain must be provided by the pre-driver stage. (Refer to Fig. 26) The gain for each stage can be calculated as follows.

$$\text{Point a} \dots \dots \dots A_{va} \approx 20 \log \frac{R_L}{R_S} \approx 20 \log \frac{R_{405}}{R_{409}} \approx 20 \log \frac{2.7 \times 10^3}{33} \approx 38.3 \text{ dB}$$

$$\text{Point b} \dots \dots \dots A_{vb} \approx 20 \log \frac{R_L}{R_E} \approx 20 \log \frac{R_{423}}{R_{427}} \approx 20 \log \frac{680}{510} \approx 2.5 \text{ dB}$$

$$\text{Point c} \dots \dots \dots A_{vc} \approx 20 \log \frac{R_L}{R_E} \approx 20 \log \frac{R_{453}}{R_{445}} \approx 20 \log \frac{82 \times 10^3}{120} \approx 56.7 \text{ dB}$$

Distribution of Voltage Amplification Within Main Amplifier Fig. 26

The overall gain of the main (V) amplifier is as follows.

$$Av\sigma \approx \frac{A}{1 + A\beta}$$

As is evident from the characteristics chart for TR403 (2SK270BL) (Fig. 25), A is 10n(A) (with ID = 3mA and VDS = 26V).

Further calculation results in

$$Av\sigma \approx \frac{A}{A\beta} \approx \frac{1}{\beta} \quad \beta = \frac{R469}{R469 + R485}$$

$$Av\sigma \approx \frac{R469 + R485}{R469} \approx \frac{560 + 10 \times 10^3}{560} \approx 25.5 \text{ dB}$$

Therefore the NFB amount is 70dB.

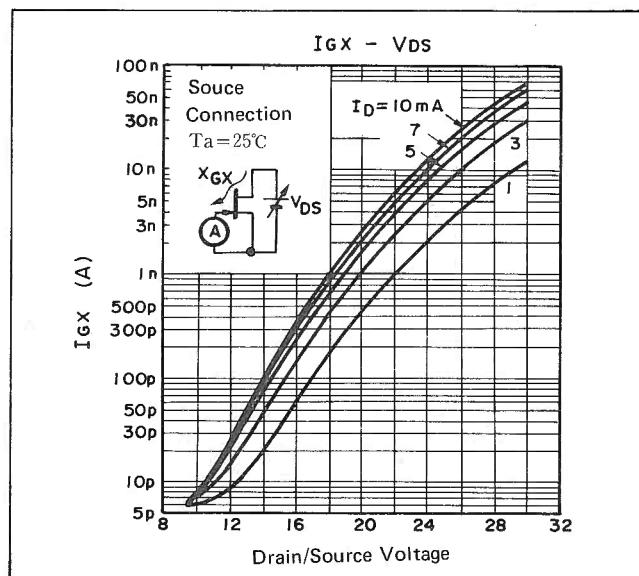

Fig. 27

5. Point e: Forms the driver stage in combination with TR423, TR425, TR501, TR503 of the main (P) amplifier circuit.

This driver stage supplies the necessary drive current to the output transistor base from the signal amplified in the initial and pre-driver stages. It is connected to the output transistors in a Darlington configuration. (Fig. 28) the circuit consisting of TR421, R457, D407, VR401, and R459 supplies an idling current to the base of the driver stage. In case of a push-pull circuit without idling current, such as shown in Fig. 29, crossover distortion arises and good sound quality cannot be obtained. Crossover distortion is a kind of switching distortion which invariably arises in a push-and-pull circuit of the type shown in Fig. 29, when the NPN and PNP transistors switch ON and OFF. However, by applying a current to the transistor base, the transistor will switch ON before the actual signal has to be processed. Thus the shift in the waveform crossover points can be prevented and a distortion-free sine wave is obtained at the output when a sine wave is applied to the input, as shown in Fig. 30. Crossover distortion is thus eliminated.

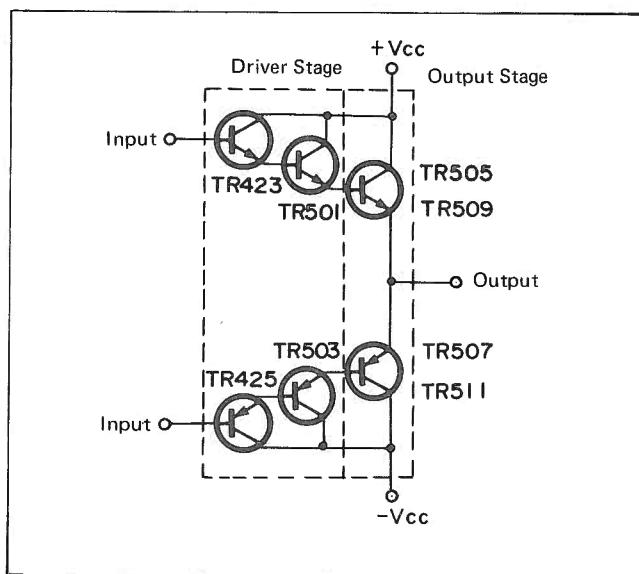

Fig. 28

The setting principle of the idling current is shown in Fig. 31. As the transistor voltage V_{BE} is 0.6V, the current flowing between A and B is $I = 0.6/R$. Therefore the voltage V_2 is $I_0 \times 2R$ it follows

$$V_2 = 0.6/R \times 2R \\ = 1.2 [V]$$

The A-11 employs the circuit shown in Fig. 32. The VR permits adjustment of idling current. D407 is attached to the heatsink of the output stage and serves to regulate the idling current depending on the temperature change V_{BE} of the output transistors. The temperature-dependant characteristics of D407 (STV-3H) are shown in Fig. 33. When the temperature rises, the voltage decreases, and vice versa.

6. Point f: DC servo circuit consisting of an inverter amplifier, to cut off low frequencies when applying negative feedback. The feedback signal is taken from the output stage.

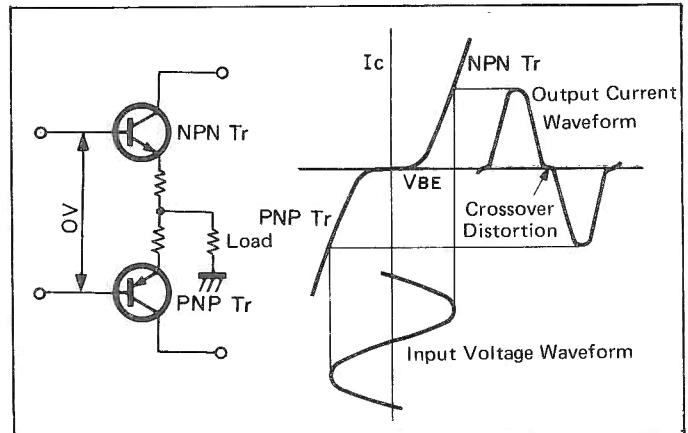

Fig. 29

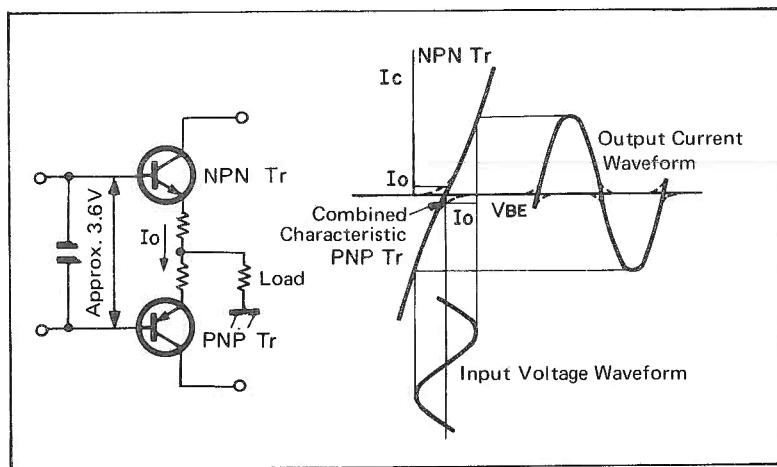

Fig. 30

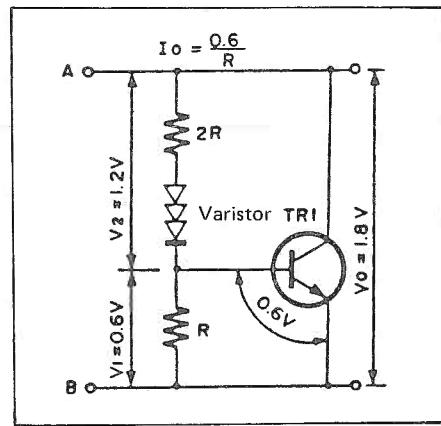

Fig. 31

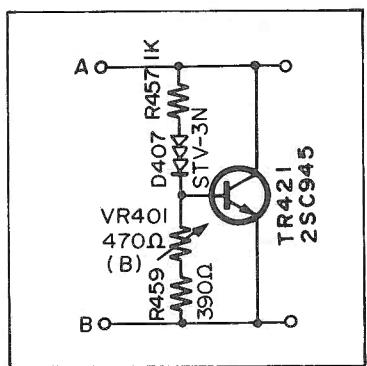

Fig. 32

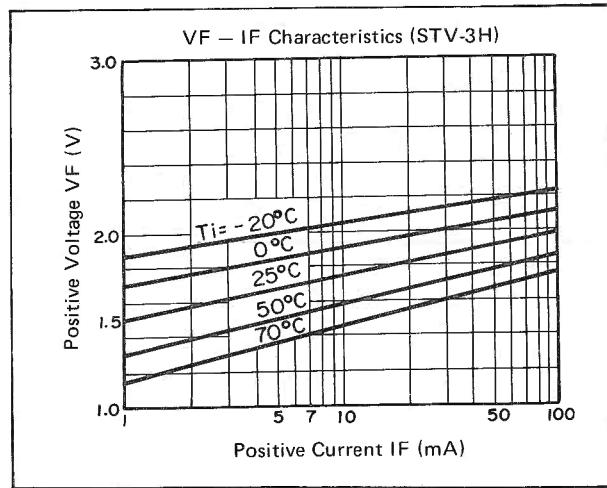

Fig. 33

<Main (P) Amplifier Circuit>

The main (P) amplifier is constructed as a complementary type SEEP circuit. Together with TR423 and TR425 of the preceding stage, TR501 and TR503 form the driver stage, and TR505, TR507, TR509, and TR511 form the output stage. The peak current flowing in the output stage with a load of 4 ohms at the 140W output of the A-11 is approxi-

mately 8.4A. In order to sustain this large current, two transistors of equal characteristics are employed in each SEEP circuit. This configuration is called para-push circuit. (Fig. 34) TR513 serves to detect any excessive current flow in the output stage and drive the protector circuit. (Fig. 34)

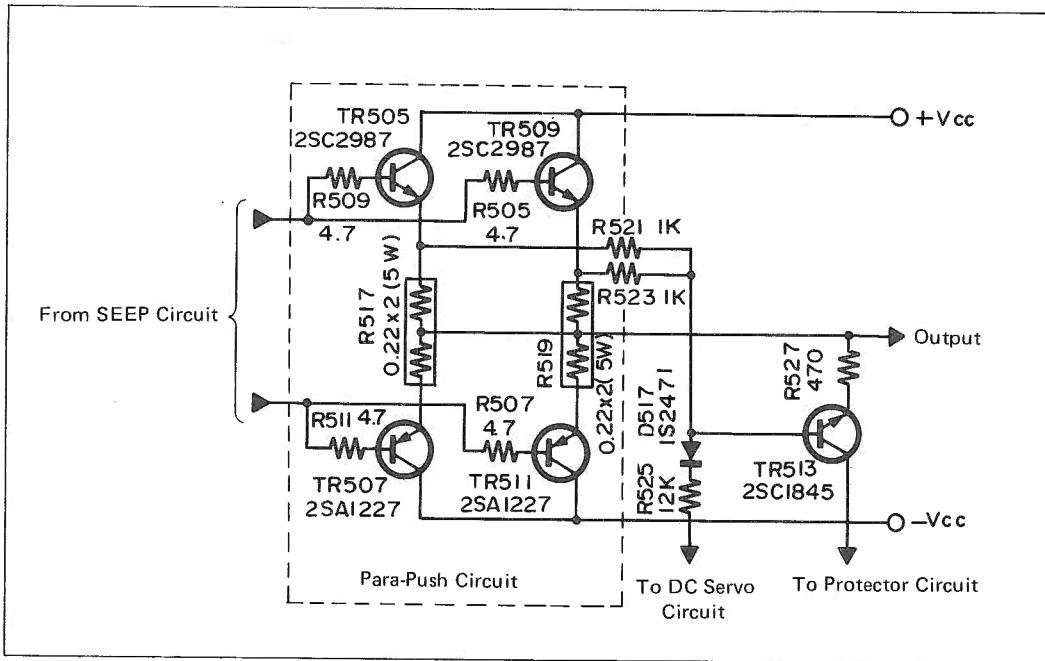

Fig. 34

<Protector Circuit>

The protector circuit consists of IC801, IC802, TR802, TR803, R101, R802, and R803. IC801 serves to prevent

excessive current from flowing to the loudspeakers, and IC802 operates the power ON/OFF muting. (Fig. 35)

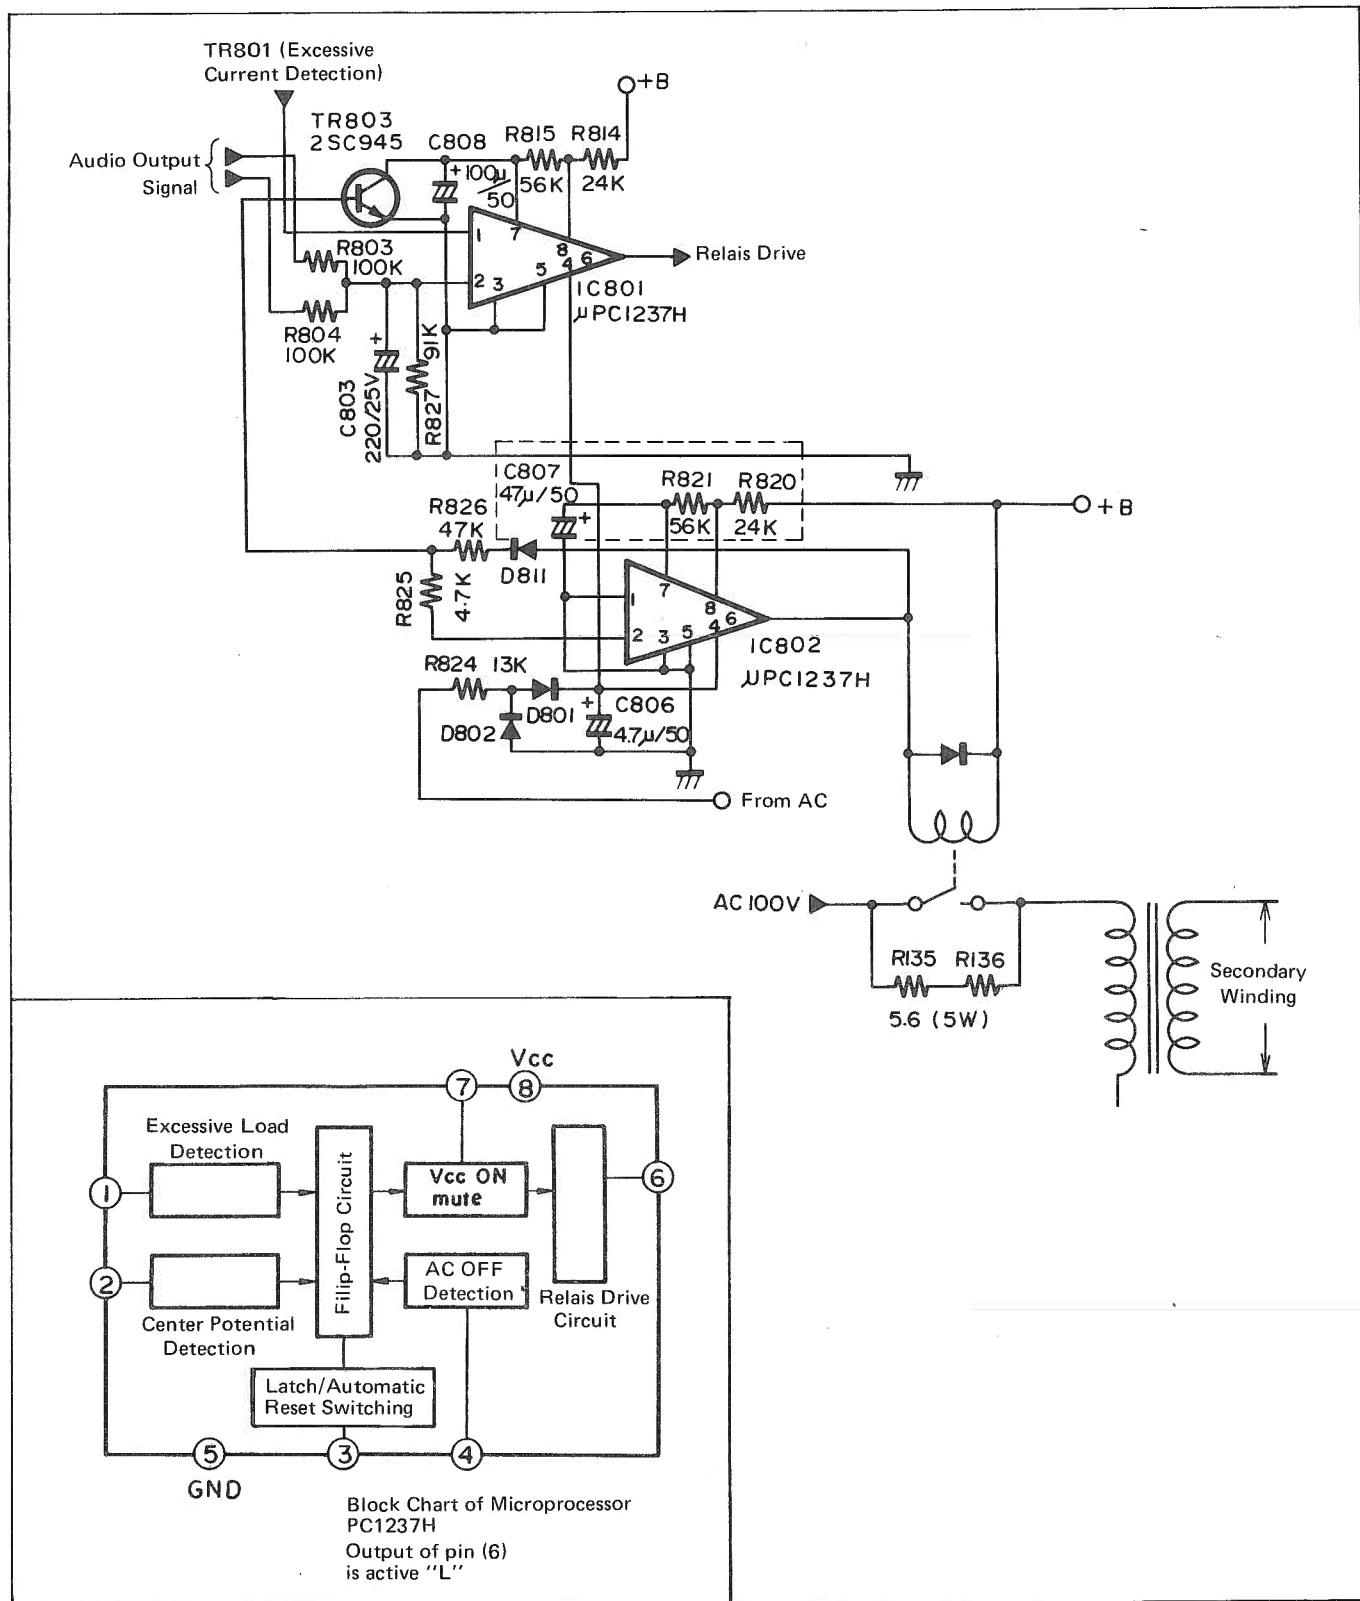

Fig. 36

Fig. 35

<Reserve II Power Supply>

The power supply rectifies the AC current and feeds it to the respective circuits. However, the waveform of the current provided by the power supply is not true DC but contains certain fluctuations, as shown in Fig. 37. The less fluctuations are present in the supply voltage, the better the sound quality of an amplifier will be. The A-11 employs the so-called Reserve II power supply principle to provide a very close equivalent of DC current. The basic principle of this circuit is shown in Fig. 38.

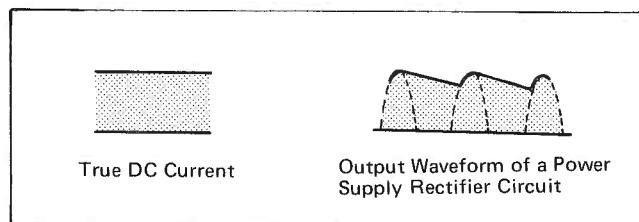

Fig. 37

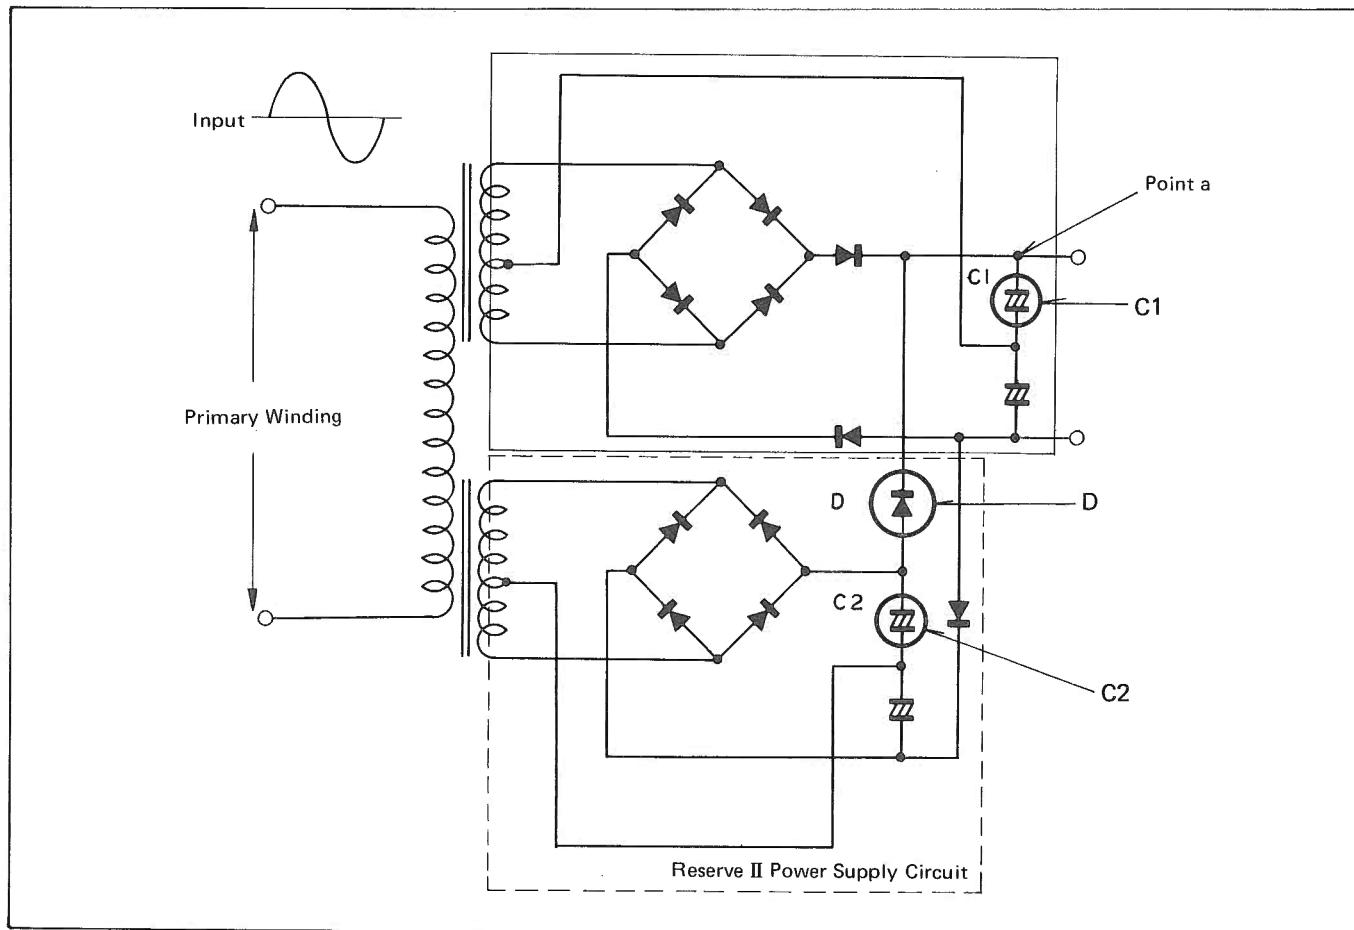

Fig. 38

With an ordinary power supply (solid line rectangle in Fig. 38), the output waveform at point (a) is as shown by the solid line in Fig. 39. By adding to this circuit another circuit with identical characteristics (dotted line rectangle in Fig. 38), the waveform at point (a) becomes as shown by the dotted line in Fig. 39.

This makes use of the characteristics of diode D, which cause C2 to discharge its electric potential when the potential of C1 becomes lower than that of C2. Thereby C1 is continuously being charged, which creates a power supply voltage close to a straight line. In this way, the A-11 achieves superior sound quality which cannot be fully expressed by more specifications.
