^a Subjected to special controls on critical characteristics, environmental tests (shock, fatigue, vibration, altitude), and special life tests.

^b The number identifies a particular laboratory tube design but the number and identifying data are subject to change. No obligations are assumed as to future manufacture unless otherwise arranged.

^c Copies are available from: Specifications Division, Naval Supply Depot, 5801 Tabor Ave., Philadelphia, Pa. 19120.

^d Developed under Buships, U.S. Navy contract.

^e Bogey heater warm-up time = 8 sec. for series-heater-string applications.

^f For fixed-bias/cathode-bias operation; single values are for either. For industrial and military types, at T_{shell} = 150° C; max. T_{shell} with R_{g1} derating = 250° C. For entertainment types, at T_{shell} = 135° C.

^g Intended for applications where it is desired to avoid use of a tube socket (such as printed-circuit-board applications; short-life, no-replacement applications; and applications at frequencies where reactances caused by use of a socket would result in substantially-lowered tube performance). These types differ primarily from their respective prototypes in that they do not have either indexing lugs or base skirt, and in place of base pins have leads of length 0.750 inch min. RCA will entertain requests for other versions of specific prototypes having any number of long leads up to a maximum of 3 per electrode.

^h Intended for hybrid-equipment applications. RCA will entertain requests for other versions of specific prototypes having a bogey E_f ≤ 13.5 V with a corresponding bogey I_f such that cathode temperature is held constant.

^k For DF ≤ 0.01; for DF > 0.01 and ≤ 0.5, i_{km} derating is required.

^m For metal-shell-to-ceramic-insulator seal temperatures up to 100° C. Higher temperatures permissible with P_{g1} derating.

ⁿ For top-cap-to-ceramic-insulator seal temperatures up to 150° C. Higher temperatures permissible with P_b derating.

^p With series plate-circuit resistance = 5000 ohms min.

^q A mechanically-modified Type 8058 nuvistor tube is utilized in each amplifier stage. The plate and one end of the heater of each tube are connected to a common dc-ground terminal (tab) on the metal shell of the amplifier; the cathode and other end of the heater are brought out to separate terminals through 470-pF feed-thru capacitors; the grid has a separate terminal and is bypassed with a 1000-pF capacitor. Each amplifier or amplifier-filter combination has an input impedance of 50 ohms, and is designed for use with a load having an impedance of 50 ohms. RF terminals on each filter or amplifier are designed to mate with screw-on connectors Sealectro Corp. (225 Hoyt St., Mamaroneck, N.Y. 50944) Part No. 50 007 0000, or equivalent. For rigid filter-to-amplifier interconnection, Sealectro 50 073 000, 50 073 0029, or equivalent,

may be used; for flexible interconnection, RG 188/U coaxial cable is recommended. RCA will entertain requests for other TRF Amplifiers having a center frequency within the range of 470 Mc to 1200 Mc.

^r At T_A = 25°C and under same conditions as shown for Electrical Chars.

^s Amplification (voltage gain) at center frequency f_o.

^t Change in f_o; measured as average of Δf_L and Δf_U at -6 db level.

^u Change in A_o from its value at T_A = 25°C.

^v Exclusive of terminals.

NUVISTOR-TUBE RELIABILITY

Production Tests (At Max.-Rated P_b)

Based on over 1,662,000 tube-hours of regular-production life tests, nuvistor type 7586 has had an observed Failure Rate of 0.54% per 1000 hours during the first 5000 hours of operation at maximum-rated plate-dissipation conditions ($E_f = 6.3$ volts, $E_b = 100$ volts, $E_c = -1.85$ volts, $R_g = 0.5$ megohm, $E_{hk} = 100$ volts, $P_b = 1$ watt and $T_E = 150^\circ\text{C min.}$)

Engineering-Evaluation Tests (At Reduced P_b)

Based on over 1,541,000 tube-hours of engineering-evaluation life tests, nuvistor type 7586 has had an observed Failure Rate of 0.065% per 1000 hours, out to 20,000 hours of operation at reduced plate-dissipation (normal-operation) conditions ($E_f = 6.3$ volts, $E_{bb} = 75$ volts, $R_k = 100$ ohms, $R_g = 0.5$ megohm, $P_b = 0.75$ watt, and $T_E = 150^\circ\text{C min.}$)

UNIFORMITY OF NUVISTOR-TUBE CHARACTERISTICS

The critical characteristics of RCA nuvistor tubes have an extremely high degree of uniformity from tube to tube, both initially and throughout life when compared to conventional electron tubes. This exceptional uniformity results from the unique nuvistor-tube design, the special methods of assembly and processing, and a rigorous Quality-Assurance Program. Industrial and Military types are subjected, on a statistical-lot-sampling basis, to Initial Variables Controls to assure that the spread of critical characteristics is narrow and that the sample average is close to the established bogey value. In addition, Life-Test end-points assure that (1) the Transconductance Change with Operating Time for an individual sample tube and the Sample Average of these individual changes, are small and (2) the Useful Power Output for class C types is above an established minimum value.

NUVISTOR TUBES and NUCLEAR RADIATION

Pulse Nuclear Irradiation

Nuvistor tubes have been operated as af-amplifier tubes and monitored before, during, and after exposure to pulse nuclear radiation having a Peak Fast-Neutron Flux of 10^{15} neutrons per square centimeter per second and a Peak Gamma Intensity of 10^7 roentgens per second.

The transient response of all tubes monitored followed the nuclear-radiation pulse and returned to normal, with no permanent damage to the tubes.

Steady-State Nuclear Irradiation

Type 7586 nuvistor tubes have been operated, for 3 hours, in a nuclear-radiation environment having a constant Fast-Neutron Flux of 10^{13} neutrons per square centimeter per second and a Gamma Intensity of 10^8 roentgens per second.

During the 3-hour exposure to nuclear radiation, the tubes continued to operate with no permanent damage.
